## NOVEL HEDGEHOG-DERIVED POLYPEPTIDES

### BACKGROUND OF THE INVENTION

#### 1. *Field of the Invention*

This invention relates generally to the field of protein processing and protein signalling pathways and specifically to two novel proteins having distinct activities, which are  
5 derived from a common hedgehog protein precursor.

#### 2. *Description of the Related Art*

Embryologists have long performed experimental manipulations that reveal the striking abilities of certain structures in vertebrate embryos to impose pattern upon surrounding  
10 tissues. Speculation on the mechanisms underlying these patterning effects usually centers on the secretion of signaling molecule that elicits an appropriate response from the tissues begin patterned. More recent work aimed at the identification of such signaling molecules implicates secreted proteins encoded by individual members of a small number of gene families. One such family of proteins which may have an  
15 influential effect upon patterning activities are those proteins encoded by the *hedgehog* gene family.

The *hedgehog* (*hh*) gene was initially identified based on its requirement for normal segmental patterning in *Drosophila* (Nüsslein-Volhard, C. & Wieschaus, E, *Nature* 287:795-801, 1980). Its functions include local signaling to coordinate the identities of  
20 adjacent cells within early embryonic segments (Hooper, J.E., & Scott, M.P. *Early Embryonic Development of Animals*, pp.1-48, 1992) and a later function in cuticle patterning that extends across many cell diameters (Heernskerk, J. & DiNardo, S., *Cell*, 76:449-460, 1994). The *hh* gene also functions in the patterning of imaginal precursors of adult structures, including the appendages and the eye (Mohler, J. *Genetics*, 120:1061-

-2-

1072, 1988; Ma, *et al.*, *Cell*, 75:927-938, 1993; Heberlein, *et al.*, *Cell*, 75:913-926, 1993; Tabata, T. & Kornberg, T.D., *Cell*, 76:89-102, 1992; Basler, K. & Struhl, G., *Nature*, 368:208-214, 1994). Genetic and molecular evidence indicates that *hedgehog* proteins are secreted and function in extracellular signaling (Mohler, J., *supra*; Lee, *et al.*, *Cell*, 71:33-50, 1992; Taylor, *et al.*, *Mech. Dev.*, 42:89-96, 1993).

In vertebrates activities encoded by *hh* homologues have been implicated in anterior/posterior patterning of the limb (Riddle, *et al.*, *Cell*, 75:1401-1416, 1993; Chang, *et al.*, *Development*, 120:3339, 1994), and in dorsal/ventral patterning of the neural tube (Echelard, *et al.*, *Cell*, 75:1417-1430, 1993; Krauss, *et al.*, *Cell*, 75:1431-1444, 1993; Roelink, *et al.*, *Cell*, 76:761-775, 1994).

The vertebrate ventral midbrain contains neurons whose degeneration or abnormal function are linked to a number of diseases, including Parkinson's disease and schizophrenia. It is known that motor neurons develop in close proximity to the floor plate in the ventral midbrain. Midbrain projections to the striatum are involved in the control of voluntary movement (Bjorklund and Lindvall, In: *Handbook of Chemical Neuroanatomy*, eds., Bjorklund, *et al.*, Amsterdam: Elsevier, pp55-122, 1984) and loss of these neurons results in the motor disorders of Parkinson's disease (Hirsch, *et al.*, *Nature*, 334:345, 1988). Midbrain dopaminergic neurons that innervate limbic structures and the cortex influence emotional and cognitive behavior, respectively, and abnormal function of these neurons has been associated with schizophrenia and drug addiction (Seeman, *et al.*, *Nature*, 365:441, 1993).

While the molecular nature of the factors that specify neuronal cell fate have not been established, members of the transforming growth factor- $\beta$  (TGF- $\beta$ ) (Lyons, *et al.*, *Trends in Genetics*, 7:408, 1991) or the hedgehog protein family (Smith, J.C., *Cell*, 76:193, 1994) may possess the characteristics expected from such factors as they participate in specification of cell fate, mediate inductive interactions between tissues, and in many cases act at a distance of only a few cell diameters.

-3-

The present invention establishes that *hh* activities encoded by these genes play a crucial role in early patterning of the developing eye and in patterning of the brain. For the first time, the invention shows that internal cleavage of hedgehog protein product is critical for full function, and that the two novel products of this auto-proteolytic cleavage display distinguishable activities, thus demonstrating that *hh* signaling activity is a composite effect of two separate signaling proteins that derive from a common *hh* protein precursor.

5 In so doing, the invention provides the means for specific patterning and proliferation of desired neuronal cell types for addressing disorders which arise from neuronal degeneration or abnormal function.

## SUMMARY OF THE INVENTION

The present invention is based on the seminal discovery that hedgehog proteins undergo auto-proteolytic cleavage which results in two separate proteins having distinct functional and structural characteristics. The two polypeptides, referred to as the "N" and "C" fragments of hedgehog, or N-terminal and C-terminal fragments, respectively, are produced after specific cleavage at a G<sup>1</sup>CF site recognized by the autoproteolytic domain in the native protein.

Thus, in one embodiment, the invention provides a substantially pure polypeptide characterized by having an amino acid sequence derived from amino terminal amino acids of a hedgehog protein and having at its carboxy terminus, a G<sup>1</sup>CF cleavage site specifically recognized by a proteolytic activity of the carboxy terminal fragment of the native hedgehog polypeptide.

In another embodiment, the invention provides a substantially pure polypeptide characterized by having an amino acid sequence derived from carboxy terminal amino acids of a hedgehog protein and having at its amino terminus, a G<sup>1</sup>CF cleavage site specifically recognized by a proteolytic activity of the carboxy terminal fragment of the native hedgehog polypeptide.

The invention also provides a method for modulating proliferation or differentiation of neuronal cells, comprising contacting the cells with a hedgehog polypeptide. The native hedgehog polypeptide, the N, or the C fragment, or functional fragments derived therefrom, are most useful for the induction of proliferation or differentiation of neuronal cells substantially derived from floor plate neuronal cells.

**BRIEF DESCRIPTION OF THE DRAWINGS**

FIGURE 1 shows processing of the hh protein by immunoblots (A,C) with antibodies against amino (Ab1) and carboxy-terminal (Ab2) epitopes. FIGURE 1B and D are blots of samples immunoprecipitated with Ab1 (B, lanes 7-9), Ab2 (D, lanes 19-21), or pre-immune serum (B, lanes 10-12, and D, lanes 22-24).

FIGURE 1E shows a schematic illustration of the hedgehog cleavage mechanism.

FIGURE 2 shows sequence similarity between hh proteins and serine proteases. hh protein sequences are aligned to residues 323 to 329 of the *D. melanogaster* protein and numbered as positions 1 to 7 (group A). The catalytic histidines of mammalian serine proteinases (group B) are aligned to the invariant histidine at position 7 in hh proteins.

FIGURE 3 shows autoproteolysis of the hh protein. 3A shows a coomassie blue stained polyacrylamide gel showing production and purification of His<sub>6</sub>-U and His<sub>6</sub>-U<sub>H329A</sub> proteins from *E. coli*. Samples were molecular weight markers (lanes 1 and 2); lysates of *E. coli* cells carrying the His<sub>6</sub>-U expression construct without (lane 3) and with (lane 4) induction by IPTG; purified His<sub>6</sub>-U protein (lane 5); lysates of *E. coli* cells that carry the His<sub>6</sub>-U<sub>H329A</sub> expression construct without (lane 6) and with (lane 7) induction by IPTG; purified His<sub>6</sub>-U<sub>H329A</sub> protein (lane 8). FIGURE 3(B) is an immunoblot detected with Ab2 showing transfected S2 cells induced to express hh (lane 1); His<sub>6</sub>-U and His<sub>6</sub>-U<sub>H329A</sub> proteins incubated in cleavage reaction buffer for 0 hours (lanes 2 and 5), for 20 hours (lanes 3 and 6), and for 20 hours in the presence of 20 mM TAME (a serine protease inhibitor) (lanes 4 and 7).

FIGURE 4 shows autoproteolytic functions of *Drosophila* (4A-C) and zebrafish (D) hh proteins map to the carboxy terminal fragments by in vitro translations of wild-type and mutant hh proteins. The locations of mutations and cleavage sites (arrows) in these proteins are illustrated schematically in 4E.

-6-

FIGURE 5 shows immunoblots showing heat shock induced expression of wild type and H329A mutant hh proteins in *Drosophila* embryos (A) and (B) are immunoblots developed using Ab1 and Ab2 antibodies, respectively. Lanes 1 and 6, induced untransfected S2 cells; lanes 2 and 7, transfected S2 cells induced to express *hh*; lanes 3 and 8, heat shocked wild-type embryos; lanes 4 and 9, heat shocked *hshh* embryos; lanes 5 and 10, heat shocked *hshh* H329A embryos.

FIGURE 6 shows *in situ* hybridization showing the embryonic effects of ubiquitously expressed wild type and H329A hh proteins. FIGURE 6 shows the embryonic distribution of *wingless* (*wg*) RNA as revealed by in situ hybridization is shown in (A) wild-type (homozygous *y<sup>1</sup> w<sup>1118</sup>*), (B) *hshh*, and (C) *hshh* H329A embryos that were exposed to two 10 minute heat shocks separated by a 90-minute recovery period (33). Wild-type embryos showed little change in *wg* expression, whereas the wild-type protein and, to a lesser extent, the H329A protein each induced ectopic *wg* expression (Table 1). Panels (D), (E), and (F) show the dorsal surfaces of *y<sup>1</sup> w<sup>1118</sup>*, *hshh*, and *hshh* H329A larvae, respectively, at the level of the fourth abdominal segment. These larvae were shocked for 30 minutes as embryos and allowed to complete embryogenesis. Cuticle cell types (1°, 2°, 3°, and 4°) are labeled as described (J. Heemskerk and S. DiNardo, *Cell* 76, 449, 1994). Note the expansion of 2° cell types (naked cuticle) at the expense of 3° and some 4° types in the *hshh* embryo (E) under conditions where the phenotype of *hshh* H329A embryos (F) is identical to that of control embryos (D).

FIGURE 7 shows X-gal staining to show imaginal disc effects of ubiquitous wild type and H329 hh proteins. X-gal staining was used to follow expression of *wg* (A-C) or *dpp* (D-L) in imaginal discs of late third-instar larvae that carry *wg-lacZ* or *dpp-lacZ* reporter genes. Leg (A-F), wing (G-I) and eye-antennal discs (J-L) from control larvae (A, D, G, J), larvae carrying the *hshh* transgene (B, E, H, K) and larvae carrying the *hshh* H329A transgene (C, F, I, L) are displayed. In all panels anterior is to the left.

-7-

FIGURE 8 (A) and (B) are immunoblots of cell pellets (lane 1) or supernatants (lane 2) from transfected S2 cell cultures expressing HH protein, developed with Ab1 (A) and Ab2 (B). Samples in each lane were from the same volume of resuspended total culture. Whereas N remained mostly associated with the cell pellet (compare lanes 1 and 2 in A), C was nearly quantitatively released into the supernatant (compare lanes 1 and 2 in B). U displayed partitioning properties in between those of N and C (A and B). (C) demonstrates the heparin binding activity of various HH protein species generated by in vitro translations with microsomes (38). Samples were: total translation mix (lane 1); supernatant after incubation with heparin agarose or agarose (control) beads (lanes 2 and 4); and material eluted from heparin agarose or agarose beads after washing (lanes 3 and 5). F, U, N<sub>ss</sub> and N fragments are depleted from reactions incubated with heparin agarose but not agarose beads (compare lanes 2 and 4 to 1), and the same species subsequently can be eluted from the heparin agarose but not the agarose beads (compare lanes 3 and 5 with lane 1).

FIGURE 9 shows the differential localizations of N and C in embryos by in situ localization of the *hh* transcript. Fig. 9 (A) is shown in comparison to the distribution of N and C epitopes detected with Ab1 and Ab2 in panels (B) and (C), respectively. Note that the distribution of N and C epitopes span approximately one-third and one-half of each segmental unit respectively, while the transcript is limited to approximately one-quarter of each unit. In (D), the localization of C epitopes in embryos homozygous for the *hh*<sup>13E</sup> allele is detected with the use of Ab2. C epitopes in this mutant, which displays impaired auto-proteolytic activity (see text), are more restricted, and resemble the wild-type localization of N. Homozygous *hh*<sup>13E</sup> embryos were identified by loss of a marked balancer from a heterozygous parent stock. All embryos are at mid to late stage 9 (extended germ-band).

FIGURE 10 shows a signal relay versus dual function models for hh protein action. In Fig. 10 (A), the long-range effects of hh signaling are achieved indirectly through short-range induction of a second signaling molecule (X). Based on its biochemical properties

-8-

and its restricted tissue localization, N is presumed to represent the active short-range signal while the role of C would be limited to supplying the catalytic machinery required for biogenesis of N. In (B), the long- and short-range signaling functions of hh are supplied by the N and C proteins derived by internal auto-proteolysis of the U precursor.

5 N is implicated in short-range signaling by retention near its cellular site of synthesis, while C is less restricted in its distribution and would execute long-range signaling functions. In both models, auto-proteolysis is required to generate fully active signaling proteins.

FIGURES 10 C and D show an immunoblot of the N fragment synthesized from a wild type construct (C) or a construct lacking the C domain (D).

10

FIGURES 11 A and B show the nucleotide and deduced amino acid sequences for partial human *hh* clones.

FIGURE 12 A and B show *in vitro* cleavage reactions of a *Drosophila hh* protein produced in *E. coli* and purified to homogeneity. FIGURE 12, Panel A shows a time course of cleavage after initiation by addition of DTT. Panel B shows incubations of concentrations ranging over three order of magnitude for a fixed time period (four hours), with no difference in the extent of conversion to the cleaved form. Panel C shows the sequence around the cleavage site as determined by amino-terminal sequence of the cleaved fragment C. The cleavage site is denoted by the arrow, and the actual residues sequenced by Edman degradation of the C fragment are underlined. Panel C also shows an alignment of all published vertebrate *hh* sequences plus some of unpublished sequences from fish and *Xenopus*. The sequences shown correspond to the region of *Drosophila hh* where the cleavage occurs, and demonstrates the absolute conservation of the Gly-Cys-Phe sequence at the site of cleavage. Panel D shows a SDS-PAGE gel loaded with *in vitro* transcription/translation reactions as described in the previous Examples, using various *hh* genes as templates. *dhh* is *Drosophila*, *twhh* and *zfshh* are the *twiggy-winkle* and *sonic hh* genes of the zebrafish, and *mshh* is the *shh/Hgh-1/vhh-1*

15

## DETAILED DESCRIPTION OF THE INVENTION

The present invention provides two novel polypeptides originally derived from a single precursor protein, both of which have distinct structural and functional characteristics. The proteins are derived from a hedgehog protein and can be naturally produced by auto-  
5 proteolytic cleavage of the full-length hedgehog protein. Based on evidence provided herein, which indicates that hedgehog precursor protein and the auto-proteolytic products of hedgehog precursor protein are expressed in the floorplate of the ventral midline of the neural tube and notochord, the invention now provides a method for the induction of proliferation or differentiation of neuronal cells associated with or in close proximity to  
10 the floorplate and notochord.

In a first embodiment, the invention provides a substantially pure polypeptide characterized by having an amino acid sequence derived from amino terminal amino acids of a hedgehog protein and having at its carboxy terminus, a glycine-cysteine-phenylalanine (G↓CF) cleavage site specifically recognized by a proteolytic activity of the carboxy  
15 terminal fragment of the native hedgehog polypeptide. This fragment is denoted the N-terminal fragment or polypeptide or "N", herein. For example, in the case of the *Drosophila* hedgehog, the N fragment includes amino acids 1-257 of hedgehog protein, wherein amino acids 85-257 have a molecular weight of about 19 kD by non-reducing SDS-PAGE (Amino acid residue numbers 1-257 include non-structural features such as  
20 signal sequences.). The G↓CF cleavage site in *Drosophila* hedgehog precursor protein occurs at amino acid residues 257-259. Those of skill in the art will be able to identify the G↓CF cleavage site in other hedgehog genes, as the amino acid location will be similar and the site will be specifically recognized by the autoproteolytic activity of the corresponding C fragment.

25 The N-terminal polypeptide is also characterized by being cell-associated in cells expressing the polypeptide *in vitro*, and being specifically localized in vertebrate or *Drosophila* cells or embryos, for example. In other words, this N-terminal fragment of

-12-

hedgehog, remains close to the site of cellular synthesis. The association of N with the cell is a result of the processing event which involves lipophilic modification of the amino terminal domain. (See Figure 1E) This modification is initiated by the action of the carboxy terminal domain, generating a thioester intermediate; the carboxy-terminal domain thus does not act simply as a protease, although cleavage of a peptide bond does ultimately result from its action. In addition, the N fragment binds to heparin agarose *in vitro*.

The N polypeptide of the invention is characterized by having an amino acid sequence derived from amino terminal amino acids of hedgehog protein, *e.g.*, 1-257 in *Drosophila*, wherein amino acids 1-257 have a molecular weight of about 19 kD by non-reducing SDS-PAGE. The N polypeptide includes smaller fragments which retain the functional characteristics of full length N, *e.g.*, bind to heparin. The hedgehog protein from which N is derived includes, but is not limited to *Drosophila*, *Xenopus*, chicken, zebrafish, mouse, and human. Crystallographic analysis shows the structure of SHH-N includes the presence of a zinc ion. While not wanting to be bound by a particular theory, the presence of the zinc ion is suggestive of zinc hydrolase activity. Zinc hydrolases include proteases such as carboxypeptidase A and thermolysin, lipases such as phospholipase C, and other enzymes such as carbonic anhydrase. Alterations in the zinc hydrolase site of the amino terminal signaling domain may be useful for modulating the range of diffusion of a hedgehog protein or to alter the signaling characteristics of the amino terminal signaling domain. For example, a mutation in the zinc hydrolase site may result in a tethered protein where ordinarily the protein is secreted at a distance. The result would be induction of a cell type not typically induced. Alteration in the zinc site may result in a molecule capable of inducing motor neurons and not floor plate, and vice versa.

The identification of a cell-surface, or extracellular matrix localization of N and its expression in notochord and floor plate-associated cells, provides a means for isolation or specific selection of cells expressing N, *e.g.*, to isolate a notochord sample or to isolate

-13-

floor plate cells. In addition, antibodies directed to N are useful for histological analysis of tissues suspected of expressing N protein.

The invention also provides a substantially pure polypeptide characterized by having an amino acid sequence derived from carboxy terminal amino acids of a hedgehog protein and having at its amino terminus a G↓CF cleavage site specifically recognized by a proteolytic activity of the carboxy terminal fragment of the native hedgehog polypeptide. This fragment is denoted the C-terminal fragment or polypeptide or "C", herein. For example, in *Drosophila* this "C" polypeptide derives from the C-terminal domain of hedgehog precursor protein beginning at amino acid residue 258, wherein the full length C-terminal domain has a molecular weight of about 25 kD by non-reducing SDS-PAGE, a histidine residue at position 72, and has protease activity. The G↓CF cleavage site specifically recognized by the proteolytic activity of the carboxy terminal fragment of the native hedgehog polypeptide is located at amino acid residues 257-259. As described above for the N fragment, now that the present invention has shown the precise cleavage recognition site for the autoproteolytic domain of hedgehog, those of skill in the art can readily discern the cleavage site in other hedgehog proteins thereby allowing the ready identification of any N or C polypeptide of any hedgehog precursor protein.

The "C" polypeptide of the invention is derived from the C-terminus of a hedgehog precursor protein, beginning at the autoproteolytic cleavage site identified at the GCF amino acid sequence, which in *Drosophila* corresponds to amino acids 257-259. In *Drosophila* the histidine residue found invariably at amino acid residue 329 of the native hedgehog protein, and at amino acid residue 72 of the C polypeptide, is essential for autoproteolytic cleavage between amino acids 257 and 258 (G and C). Corresponding C-polypeptides of the invention will likewise contain a similarly located histidine residue which can be readily identified, such as by comparison to the *Drosophila* C-polypeptide. Among various species, the proteolytic domain can be characterized by the amino acid sequence -XTXXHLXX-.

-14-

The C polypeptide of the invention, unlike N, does not significantly bind to heparin agarose. C is characterized by being released into the culture supernatant of cells expressing C polypeptide *in vitro* and by being localized diffusely in cells and embryos. Because C polypeptide diffuses freely, it would be detectable in various body fluids and tissues in a subject. Identification of C polypeptide expression near the midline of the neural tube, as described herein, provides a useful assay for neural tube closure in an embryo/fetus, for example. The presence of C polypeptide in amniotic fluid would be diagnostic of a disorder in which the neural tube may be malformed.

Altered levels of C polypeptide in cerebrospinal fluid may be indicative of neurodegenerative disorders, for example. Because C polypeptide is released from the cell after synthesis and autoproteolysis of native hedgehog precursor polypeptide, tumors synthesizing and releasing high levels of C polypeptide would be detectable without prior knowledge of the exact location of the tumor.

C fragment is effective in inducing genes of the pituitary and anterior brain as well. In particular, induction is increased by the addition of a member of the TGF- $\beta$  family of growth factors. For example, human activin in combination with C fragment may be effective in enhancing pituitary cell growth and activity or development.

C fragment is effective in inducing posterior markers of the brain by inhibiting N. Such a fragment is exemplified in Example 18 as  $\Delta$ N-C. Therefore in another embodiment, the invention includes a polypeptide deleting amino acid residues 28-194 of X-*bhh*. (Autoproteolysis gives a C domain of 198-409 as well as a seven amino acid peptide, representing aa 24-27 and 195-197). This polypeptide blocks the activity of X-*bhh* and N in explants and reduces dorsoanterior structures in embryos. Also included are polynucleotide sequences encoding  $\Delta$ N-C.  $\Delta$ N-C is useful for increasing expression of posterior neural markers (*e.g.*, En-2, Krox-20, Xlftbox-6) and decreasing expression of anterior neural markers (*e.g.*, XANF-2, XAG-1, Otx-A) when desirable to do so to modulate neural patterning.

-15-

The term "substantially pure" as used herein refers to hedgehog N or C polypeptide which is substantially free of other proteins, lipids, carbohydrates, nucleic acids or other materials with which it is naturally associated. One skilled in the art can purify hedgehog N or C polypeptide using standard techniques for protein purification. The substantially  
5 pure polypeptide will yield a single major band on a non-reducing polyacrylamide gel. The purity of the hedgehog N or C polypeptide can also be determined by amino-terminal amino acid sequence analysis.

The invention includes a functional N or C polypeptide, and functional fragments thereof. As used herein, the term "functional polypeptide" or "functional fragment" refers  
10 to a polypeptide which possesses a biological function or activity which is identified through a defined functional assay and which is associated with a particular biologic, morphologic, or phenotypic alteration in the cell. Functional fragments of the hedgehog N or C polypeptide include fragments of N or C polypeptide as long as the activity, *e.g.*, proteolytic activity of C polypeptide remains. Smaller peptides containing the biological  
15 activity of N or C polypeptide are therefore included in the invention. The biological function, for example, can vary from a polypeptide fragment as small as an epitope to which an antibody molecule can bind to a large polypeptide which is capable of participating in the characteristic induction or programming of phenotypic changes within a cell. A "functional polynucleotide" denotes a polynucleotide which encodes a  
20 functional polypeptide as described herein.

Minor modifications of the N or C polypeptide primary amino acid sequence may result in polypeptides which have substantially equivalent activity as compared to the N or C polypeptide described herein. Such modifications may be deliberate, as by site-directed mutagenesis, or may be spontaneous. All of the polypeptides produced by these  
25 modifications are included herein as long as the proteolytic activity of C polypeptide, for example, is present. Further, deletion of one or more amino acids can also result in a modification of the structure of the resultant molecule without significantly altering its activity. This can lead to the development of a smaller active molecule which would have

-16-

broader utility. For example, it is possible to remove amino or carboxy terminal amino acids which may not be required for N or C polypeptide activity.

The N or C polypeptide of the invention also includes conservative variations of the polypeptide sequence. The term "conservative variation" as used herein denotes the replacement of an amino acid residue by another biologically similar residue. Examples of conservative variations include the substitution of one hydrophobic residue such as isoleucine, valine, leucine or methionine for another, or the substitution of one polar residue for another, such as the substitution of arginine for lysine, glutamic for aspartic acids, or glutamine for asparagine, and the like. The term "conservative variation" also includes the use of a substituted amino acid in place of an unsubstituted parent amino acid provided that antibodies raised to the substituted polypeptide also immunoreact with the unsubstituted polypeptide.

The N fragment of the invention includes both the active form of the polypeptide and the N fragment including the uncleaved signal sequence. For example, in *Drosophila* where the signal sequence is internal (at about amino acids 60-80), the entire uncleaved N fragment beginning at the initiating methionine is included in the invention. Those of skill in the art can readily ascertain the nature and location of the signal sequence by using, for example, the algorithm described in von Heijne, G., *Nucl. Acids Res.* 14:4683, (1986).

The invention also provides an isolated polynucleotide sequence consisting essentially of a polynucleotide sequence encoding a polypeptide having the amino acid sequence of N or C polypeptide of the invention. The term "isolated" as used herein includes polynucleotides substantially free of other nucleic acids, proteins, lipids, carbohydrates or other materials with which it is naturally associated. Polynucleotide sequences of the invention include DNA, cDNA and RNA sequences which encode N or C polypeptide. It is understood that all polynucleotides encoding all or a portion of N or C polypeptide are also included herein, as long as they encode a polypeptide with N or C polypeptide

-17-

activity. Such polynucleotides include naturally occurring, synthetic, and intentionally manipulated polynucleotides. For example, N or C polypeptide polynucleotide may be subjected to site-directed mutagenesis. The polynucleotide sequence for N or C polypeptide also includes antisense sequences. The polynucleotides of the invention  
5 include sequences that are degenerate as a result of the genetic code. There are 20 natural amino acids, most of which are specified by more than one codon. Therefore, all degenerate nucleotide sequences are included in the invention as long as the amino acid sequence of N or C polypeptide polypeptide encoded by the nucleotide sequence is functionally unchanged. In addition, the invention also includes a polynucleotide  
10 consisting essentially of a polynucleotide sequence encoding a polypeptide having an amino acid sequence of N or C and having at least one epitope for an antibody immunoreactive with N or C polypeptide.

The polynucleotide encoding N or C polypeptide includes the entire polypeptide or fragments thereof, as well as nucleic acid sequences complementary to that sequence. A  
15 complementary sequence may include an antisense nucleotide. When the sequence is RNA, the deoxynucleotides A, G, C, and T are replaced by ribonucleotides A, G, C, and U, respectively. Also included in the invention are fragments of the above-described nucleic acid sequences that are at least 15 bases in length, which is sufficient to permit the fragment to selectively hybridize to DNA that encodes the protein under physiologi-  
20 cal conditions. Preferably, the fragments hybridize under stringent conditions.

DNA sequences of the invention can be obtained by several methods. For example, the DNA can be isolated using hybridization techniques which are well known in the art. These include, but are not limited to: 1) hybridization of genomic or cDNA libraries with probes to detect homologous nucleotide sequences; 2) antibody screening of expression  
25 libraries to detect cloned DNA fragments with shared structural features; and 3) PCR amplification of a desired nucleotide sequence using oligonucleotide primers.

Preferably the hedgehog, N, or C polynucleotide of the invention is derived from a vertebrate organism, and most preferably from human. Screening procedures which rely on nucleic acid hybridization make it possible to isolate any gene sequence from any organism, provided the appropriate probe is available. Oligonucleotide probes, which  
5 correspond to a part of the sequence encoding the protein in question, can be synthesized chemically. This requires that short, oligopeptide stretches of amino acid sequence must be known. The DNA sequence encoding the protein can be deduced from the genetic code, however, the degeneracy of the code must be taken into account. It is possible to perform a mixed addition reaction when the sequence is degenerate. This includes a  
10 heterogeneous mixture of denatured double-stranded DNA. For such screening, hybridization is preferably performed on either single-stranded DNA or denatured double-stranded DNA. Hybridization is particularly useful in the detection of cDNA clones derived from sources where an extremely low amount of mRNA sequences relating to the polypeptide of interest are present. In other words, by using stringent  
15 hybridization conditions directed to avoid non-specific binding, it is possible, for example, to allow the autoradiographic visualization of a specific cDNA clone by the hybridization of the target DNA to that single probe in the mixture which is its complete complement (Wallace, *et al.*, *Nucl. Acid Res.*, 9:879, 1981).

The development of specific DNA sequences encoding hedgehog can also be obtained  
20 by: 1) isolation of double-stranded DNA sequences from the genomic DNA; 2) chemical manufacture of a DNA sequence to provide the necessary codons for the polypeptide of interest; and 3) *in vitro* synthesis of a double-stranded DNA sequence by reverse transcription of mRNA isolated from a eukaryotic donor cell. In the latter case, a double-stranded DNA complement of mRNA is eventually formed which is generally referred  
25 to as cDNA.

Of the three above-noted methods for developing specific DNA sequences for use in recombinant procedures, the isolation of genomic DNA isolates is the least common.

-19-

This is especially true when it is desirable to obtain the microbial expression of mammalian polypeptides due to the presence of introns.

The synthesis of DNA sequences is frequently the method of choice when the entire sequence of amino acid residues of the desired polypeptide product is known. When the entire sequence of amino acid residues of the desired polypeptide is not known, the direct synthesis of DNA sequences is not possible and the method of choice is the synthesis of cDNA sequences. Among the standard procedures for isolating cDNA sequences of interest is the formation of plasmid- or phage-carrying cDNA libraries which are derived from reverse transcription of mRNA which is abundant in donor cells that have a high level of genetic expression. When used in combination with polymerase chain reaction technology, even rare expression products can be cloned. In those cases where significant portions of the amino acid sequence of the polypeptide are known, the production of labeled single or double-stranded DNA or RNA probe sequences duplicating a sequence putatively present in the target cDNA may be employed in DNA/DNA hybridization procedures which are carried out on cloned copies of the cDNA which have been denatured into a single-stranded form (Jay, *et al.*, *Nucl. Acid Res.*, 11:2325, 1983).

A preferred method for obtaining genomic DNA, for example, is Polymerase Chain Reaction (PCR), which relies on an *in vitro* method of nucleic acid synthesis by which a particular segment of DNA is specifically replicated. Two oligonucleotide primers that flank the DNA fragment to be amplified are utilized in repeated cycles of heat denaturation of the DNA, annealing of the primers to their complementary sequences, and extension of the annealed primers with DNA polymerase. These primers hybridize to opposite strands of the target sequence and are oriented so that DNA synthesis by the polymerase proceeds across the region between the primers. Since the extension products themselves are also complementary to and capable of binding primers, successive cycles of amplification essentially double the amount of the target DNA synthesized in the previous cycle. The result is an exponential accumulation of the specific target fragment, approximately  $2^n$ , where  $n$  is the number of cycles of amplification performed (see PCR

Protocols, Eds. Innis, *et al.*, Academic Press, Inc., 1990, incorporated herein by reference).

A cDNA expression library, such as  $\lambda$ gt11, can be screened indirectly for hedgehog, N, or C polypeptides having at least one epitope, using antibodies specific for hedgehog, N, or C. Such antibodies can be either polyclonally or monoclonally derived and used to  
5 detect expression product indicative of the presence of the desired hedgehog cDNA.

The polynucleotide sequence for hedgehog, N, or C, also includes sequences complementary to the polynucleotide encoding hedgehog, N or C (antisense sequences). Antisense nucleic acids are DNA or RNA molecules that are complementary to at least  
10 a portion of a specific mRNA molecule (Weintraub, *Scientific American*, 262:40, 1990). The invention embraces all antisense polynucleotides capable of inhibiting production of hedgehog, N, or C polypeptide. In the cell, the antisense nucleic acids hybridize to the corresponding mRNA, forming a double-stranded molecule. The antisense nucleic acids interfere with the translation of the mRNA since the cell will not translate a mRNA that  
15 is double-stranded. Antisense oligomers of about 15 nucleotides are preferred, since they are easily synthesized and are less likely to cause problems than larger molecules when introduced into the target hedgehog, N, or C-producing cell. The use of antisense methods to inhibit the translation of genes is well known in the art (Marcus-Sakura, *Anal. Biochem.*, 172:289, 1988). Inhibition of target nucleotide would be desirable, for  
20 example, in inhibiting cell-proliferative disorders, such as certain tumors, which are mediated by hedgehog, N or C.

In addition, ribozyme nucleotide sequences for hedgehog, N or C are included in the invention. Ribozymes are RNA molecules possessing the ability to specifically cleave other single-stranded RNA in a manner analogous to DNA restriction endonucleases.  
25 Through the modification of nucleotide sequences which encode these RNAs, it is possible to engineer molecules that recognize specific nucleotide sequences in an RNA molecule and cleave it (Cech, *J. Amer. Med. Assn.*, 260:3030, 1988). A major advantage

-21-

of this approach is that, because they are sequence-specific, only mRNAs with particular sequences are inactivated.

There are two basic types of ribozymes namely, *tetrahymena*-type (Hasselhoff, *Nature*, 334:585, 1988) and "hammerhead"-type. *Tetrahymena*-type ribozymes recognize  
5 sequences which are four bases in length, while "hammerhead"-type ribozymes recognize  
base sequences 11-18 bases in length. The longer the recognition sequence, the greater  
the likelihood that sequence will occur exclusively in the target mRNA species. Conse-  
quently, hammerhead-type ribozymes are preferable to *tetrahymena*-type ribozymes for  
inactivating a specific mRNA species and 18-based recognition sequences are preferable  
10 to shorter recognition sequences.

DNA sequences encoding hedgehog, N or C can be expressed *in vitro* by DNA transfer  
into a suitable host cell. "Host cells" are cells in which a vector can be propagated and  
its DNA expressed. The term also includes any progeny of the subject host cell. It is  
understood that all progeny may not be identical to the parental cell since there may be  
15 mutations that occur during replication. However, such progeny are included when the  
term "host cell" is used. Methods of stable transfer, meaning that the foreign DNA is  
continuously maintained in the host, are known in the art.

In the present invention, the hedgehog, N or C polynucleotide sequences may be inserted  
into a recombinant expression vector. The term "recombinant expression vector" refers  
20 to a plasmid, virus or other vehicle known in the art that has been manipulated by  
insertion or incorporation of the hedgehog, N or C genetic sequences. Such expression  
vectors contain a promoter sequence which facilitates the efficient transcription of the  
inserted genetic sequence of the host. The expression vector typically contains an origin  
of replication, a promoter, as well as specific genes which allow phenotypic selection of  
25 the transformed cells. Vectors suitable for use in the present invention include, but are  
not limited to the T7-based expression vector for expression in bacteria (Rosenberg, *et al.*, *Gene*, 56:125, 1987), the pMSXND expression vector for expression in mammalian

-22-

cells (Lee and Nathans, *J. Biol. Chem.*, 263:3521, 1988) and baculovirus-derived vectors for expression in insect cells. The DNA segment can be present in the vector operably linked to regulatory elements, for example, a promoter (e.g., T7, metallothionein I, or polyhedrin promoters).

5 Polynucleotide sequences encoding hedgehog, N or C can be expressed in either prokaryotes or eukaryotes, although post-translational modification of eukaryotically derived polypeptides, such as carboxylation, would occur in a eukaryotic host. Hosts can include microbial, yeast, insect and mammalian organisms. Methods of expressing DNA sequences having eukaryotic or viral sequences in prokaryotes are well known in the art.

10 Biologically functional viral and plasmid DNA vectors capable of expression and replication in a host are known in the art. Such vectors are used to incorporate DNA sequences of the invention.

Methods which are well known to those skilled in the art can be used to construct expression vectors containing the hedgehog, N or C coding sequence and appropriate

15 transcriptional/translational control signals. These methods include *in vitro* recombinant DNA techniques, synthetic techniques, and *in vivo* recombination/genetic techniques. See, for example, the techniques described in Maniatis, *et al.*, 1989 Molecular Cloning A Laboratory Manual, Cold Spring Harbor Laboratory, N.Y.

A variety of host-expression vector systems may be utilized to express the hedgehog, N

20 or C coding sequence. These include but are not limited to microorganisms such as bacteria transformed with recombinant bacteriophage DNA, plasmid DNA or cosmid DNA expression vectors containing the hedgehog, N or C coding sequence; yeast transformed with recombinant yeast expression vectors containing the hedgehog, N or C coding sequence; plant cell systems infected with recombinant virus expression vectors

25 (*e.g.*, cauliflower mosaic virus, CaMV; tobacco mosaic virus, TMV) or transformed with recombinant plasmid expression vectors (*e.g.*, Ti plasmid) containing the Hedgehog, N or C coding sequence; insect cell systems infected with recombinant virus expression

-23-

vectors (*e.g.*, baculovirus) containing the hedgehog, N or C coding sequence; or animal cell systems infected with recombinant virus expression vectors (*e.g.*, retroviruses, adenovirus, vaccinia virus) containing the hedgehog, N or C coding sequence, or transformed animal cell systems engineered for stable expression.

5 Depending on the host/vector system utilized, any of a number of suitable transcription and translation elements, including constitutive and inducible promoters, transcription enhancer elements, transcription terminators, etc., may be used in the expression vector (see *e.g.*, Bitter, *et al.*, 1987, *Methods in Enzymology*, 153:516-544). For example, when cloning in bacterial systems, inducible promoters such as pL of bacteriophage  $\gamma$ , plac,  
10 ptrp, ptac (ptrp-lac hybrid promoter) and the like may be used. When cloning in mammalian cell systems, promoters derived from the genome of mammalian cells (*e.g.*, metallothionein promoter) or from mammalian viruses (*e.g.*, the retrovirus long terminal repeat; the adenovirus late promoter; the vaccinia virus 7.5K promoter) may be used. Promoters produced by recombinant DNA or synthetic techniques may also be used to  
15 provide for transcription of the inserted hedgehog, N or C coding sequence.

In bacterial systems a number of expression vectors may be advantageously selected depending upon the use intended for the expressed. For example, when large quantities of hedgehog, N or C are to be produced, vectors which direct the expression of high levels of fusion protein products that are readily purified may be desirable. Those which  
20 are engineered to contain a cleavage site to aid in recovering are preferred. Such vectors include but are not limited to the *E. coli* expression vector pUR278 (Ruther, *et al.*, *EMBO J.*, 2:1791, 1983), in which the Hedgehog, N or C coding sequence may be ligated into the vector in frame with the lac Z coding region so that a hybrid -lac Z protein is produced; pIN vectors (Inouye and Inouye, *Nucleic Acids Res.*, 13:3101, 1985; Van Heeke and Schuster, *J. Biol. Chem.* 264:5503, 1989) and the like.  
25

In yeast, a number of vectors containing constitutive or inducible promoters may be used. For a review see, *Current Protocols in Molecular Biology*, Vol. 2, 1988, Ed. Ausubel, *et*

-24-

*al.*, Greene Publish. Assoc. & Wiley Interscience, Ch. 13; Grant, *et al.*, 1987, Expression and Secretion Vectors for Yeast, in *Methods in Enzymology*, Eds. Wu and Grossman, 31987, Acad. Press, N.Y., Vol. 153, pp.516-544; Glover, 1986, DNA Cloning, Vol. II, IRL Press, Wash., D.C., Ch. 3; and Bitter, 1987, Heterologous Gene Expression in Yeast, 5 *Methods in Enzymology*, Eds. Berger and Kimmel, Acad. Press, N.Y., Vol. 152, pp. 673-684; and *The Molecular Biology of the Yeast Saccharomyces*, 1982, Eds. Strathern, *et al.*, Cold Spring Harbor Press, Vols. I and II. A constitutive yeast promoter such as ADH or LEU2 or an inducible promoter such as GAL may be used (Cloning in Yeast, Ch. 3, R. Rothstein In: DNA Cloning Vol.11, A Practical Approach, Ed. DM Glover, 1986, IRL 10 Press, Wash., D.C.). Alternatively, vectors may be used which promote integration of foreign DNA sequences into the yeast chromosome.

In cases where plant expression vectors are used, the expression of the hedgehog, N or C coding sequence may be driven by any of a number of promoters. For example, viral promoters such as the 35S RNA and 19S RNA promoters of CaMV (Brisson, *et al.*, 15 *Nature*, 310:511, 1984), or the coat protein promoter to TMV (Takamatsu, *et al.*, *EMBO J.*, 6:307, 1987) may be used; alternatively, plant promoters such as the small subunit of RUBISCO (Coruzzi, *et al.*, *EMBO J.*, 3:1671-1680, 1984; Broglie, *et al.*, *Science*, 224:838, 1984); or heat shock promoters, *e.g.*, soybean hsp17.5-E or hsp17.3-B (Gurley, *et al.*, *Mol. Cell. Biol.*, 6:559, 1986) may be used. These constructs can be introduced 20 into plant cells using Ti plasmids, Ri plasmids, plant virus vectors, direct DNA transformation, microinjection, electroporation, etc. For reviews of such techniques see, for example, Weissbach and Weissbach, 1988, *Methods for Plant Molecular Biology*, Academic Press, NY, Section VIII, pp. 421-463; and Grierson and Corey, 1988, *Plant Molecular Biology*, 2d Ed., Blackie, London, Ch. 7-9.

25 An alternative expression system which could be used to express is an insect system. In one such system, *Autographa californica* nuclear polyhedrosis virus (AcNPV) is used as a vector to express foreign genes. The virus grows in *Spodoptera frugiperda* cells. The hedgehog, N or C coding sequence may be cloned into non-essential regions (for example

-25-

the polyhedrin gene) of the virus and placed under control of an AcNPV promoter (for example the polyhedrin promoter). Successful insertion of the hedgehog, N or C coding sequence will result in inactivation of the polyhedrin gene and production of non-occluded recombinant virus (*i.e.*, virus lacking the proteinaceous coat coded for by the polyhedrin gene). These recombinant viruses are then used to infect *Spodoptera frugiperda* cells in which the inserted gene is expressed. (*e.g.*, see Smith, *et al.*, *J. Virol.*, 46:584, 1983; Smith, U.S. Patent No. 4,215,051).

Eukaryotic systems, and preferably mammalian expression systems, allow for proper post-translational modifications of expressed mammalian proteins to occur. Eukaryotic cells which possess the cellular machinery for proper processing of the primary transcript, glycosylation, phosphorylation, and advantageously, secretion of the gene product may be used as host cells for the expression of hedgehog, N or C. Mammalian cell lines may be preferable. Such host cell lines may include but are not limited to CHO, VERO, BHK, HeLa, COS, MDCK, -293, and WI38.

Mammalian cell systems which utilize recombinant viruses or viral elements to direct expression may be engineered. For example, when using adenovirus expression vectors, the hedgehog, N or C coding sequence may be ligated to an adenovirus transcription/-translation control complex, *e.g.*, the late promoter and tripartite leader sequence. This chimeric gene may then be inserted in the adenovirus genome by *in vitro* or *in vivo* recombination. Insertion in a non-essential region of the viral genome (*e.g.*, region E1 or E3) will result in a recombinant virus that is viable and capable of expressing the protein in infected hosts (*e.g.*, see Logan and Shenk, *Proc. Natl. Acad. Sci. USA*, 81:3655, 1984). Alternatively, the vaccinia virus 7.5K promoter may be used. (*e.g.*, see, Mackett, *et al.*, *Proc. Natl. Acad. Sci. USA*, 79:7415, 1982; Mackett, *et al.*, *J. Virol.*, 49: 857, 1984; Panicali, *et al.*, *Proc. Natl. Acad. Sci. USA*, 79:4927, 1982). Of particular interest are vectors based on bovine papilloma virus which have the ability to replicate as extrachromosomal elements (Sarver, *et al.*, *Mol. Cell. Biol.*, 1:486, 1981). Shortly after entry of this DNA into mouse cells, the plasmid replicates to about 100 to 200 copies per

-26-

cell. Transcription of the inserted cDNA does not require integration of the plasmid into the host's chromosome, thereby yielding a high level of expression. These vectors can be used for stable expression by including a selectable marker in the plasmid, such as, for example, the neo gene. Alternatively, the retroviral genome can be modified for use as a vector capable of introducing and directing the expression of the hedgehog, N or C gene in host cells (Cone and Mulligan, *Proc. Natl. Acad. Sci. USA*, 81:6349, 1984). High level expression may also be achieved using inducible promoters, including, but not limited to, the metallothionine IIA promoter and heat shock promoters.

For long-term, high-yield production of recombinant proteins, stable expression is preferred. Rather than using expression vectors which contain viral origins of replication, host cells can be transformed with the hedgehog, N or C cDNA controlled by appropriate expression control elements (*e.g.*, promoter, enhancer, sequences, transcription terminators, polyadenylation sites, etc.), and a selectable marker. The selectable marker in the recombinant plasmid confers resistance to the selection and allows cells to stably integrate the plasmid into their chromosomes and grow to form foci which in turn can be cloned and expanded into cell lines. For example, following the introduction of foreign DNA, engineered cells may be allowed to grow for 1-2 days in an enriched media, and then are switched to a selective media. A number of selection systems may be used, including but not limited to the herpes simplex virus thymidine kinase (Wigler, *et al.*, *Cell*, 11: 223, 1977), hypoxanthine-guanine phosphoribosyltransferase (Szybalska and Szybalski, *Proc. Natl. Acad. Sci. USA*, 48:2026, 1962), and adenine phosphoribosyltransferase (Lowy, *et al.*, *Cell*, 22: 817, 1980) genes can be employed in tk<sup>-</sup>, hgp<sup>r</sup>t<sup>-</sup> or ap<sup>r</sup>t<sup>-</sup> cells respectively. Also, antimetabolite resistance can be used as the basis of selection for dhfr, which confers resistance to methotrexate (Wigler, *et al.*, *Natl. Acad. Sci. USA*, 77: 3567, 1980; O'Hare, *et al.*, *Proc. Natl. Acad. Sci. USA*, 78: 1527, 1981); gpt, which confers resistance to mycophenolic acid (Mulligan and Berg, *Proc. Natl. Acad. Sci. USA*, 78: 2072, 1981; neo, which confers resistance to the aminoglycoside G-418 (Colberre-Garapin, *et al.*, *J. Mol. Biol.*, 150:1, 1981); and hyg<sup>r</sup>, which confers resistance to hygromycin (Santerre, *et al.*, *Gene*, 30:147, 1984) genes. Recently, additional

-27-

selectable genes have been described, namely *trpB*, which allows cells to utilize indole in place of tryptophan; *hisD*, which allows cells to utilize histinol in place of histidine (Hartman and Mulligan, *Proc. Natl. Acad. Sci. USA*, 85:8047, 1988); and ODC (ornithine decarboxylase) which confers resistance to the ornithine decarboxylase inhibitor, 2-(difluoromethyl)-DL-ornithine, DFMO (McConlogue L., 1987, In: Current Communications in Molecular Biology, Cold Spring Harbor Laboratory ed.).

Transformation of a host cell with recombinant DNA may be carried out by conventional techniques as are well known to those skilled in the art. Where the host is prokaryotic, such as *E. coli*, competent cells which are capable of DNA uptake can be prepared from cells harvested after exponential growth phase and subsequently treated by the  $\text{CaCl}_2$  method using procedures well known in the art. Alternatively,  $\text{MgCl}_2$  or  $\text{RbCl}$  can be used. Transformation can also be performed after forming a protoplast of the host cell if desired.

When the host is a eukaryote, such methods of transfection of DNA as calcium phosphate co-precipitates, conventional mechanical procedures such as microinjection, electroporation, insertion of a plasmid encased in liposomes, or virus vectors may be used. Eukaryotic cells can also be cotransformed with DNA sequences encoding the hedgehog, N or C of the invention, and a second foreign DNA molecule encoding a selectable phenotype, such as the herpes simplex thymidine kinase gene. Another method is to use a eukaryotic viral vector, such as simian virus 40 (SV40) or bovine papilloma virus, to transiently infect or transform eukaryotic cells and express the protein. (see for example, *Eukaryotic Viral Vectors*, Cold Spring Harbor Laboratory, Gluzman ed., 1982).

Isolation and purification of microbial expressed polypeptide, or fragments thereof, provided by the invention, may be carried out by conventional means including preparative chromatography and immunological separations involving monoclonal or polyclonal antibodies.

-28-

The invention includes antibodies immunoreactive with or which bind to hedgehog, N or C polypeptide or functional fragments thereof. Antibody which consists essentially of pooled monoclonal antibodies with different epitopic specificities, as well as distinct monoclonal antibody preparations are provided. Monoclonal antibodies are made from antigen containing fragments of the protein by methods well known to those skilled in the art (Kohler, *et al.*, *Nature*, 256:495, 1975). The term antibody as used in this invention is meant to include intact molecules as well as fragments thereof, such as Fab and F(ab')<sub>2</sub>, which are capable of binding an epitopic determinant on hedgehog, N or C. The antibodies of the invention include antibodies which bind to the N or C polypeptide and which bind with immunoreactive fragments N or C.

The term "antibody" as used in this invention includes intact molecules as well as fragments thereof, such as Fab, F(ab')<sub>2</sub>, and Fv which are capable of binding the epitopic determinant. These antibody fragments retain some ability to selectively bind with its antigen or receptor and are defined as follows:

- (1) Fab, the fragment which contains a monovalent antigen-binding fragment of an antibody molecule can be produced by digestion of whole antibody with the enzyme papain to yield an intact light chain and a portion of one heavy chain;
- (2) Fab', the fragment of an antibody molecule can be obtained by treating whole antibody with pepsin, followed by reduction, to yield an intact light chain and a portion of the heavy chain; two Fab' fragments are obtained per antibody molecule;
- (3) (Fab')<sub>2</sub>, the fragment of the antibody that can be obtained by treating whole antibody with the enzyme pepsin without subsequent reduction; F(ab')<sub>2</sub> is a dimer of two Fab' fragments held together by two disulfide bonds;

-29-

- (4) Fv, defined as a genetically engineered fragment containing the variable genetically fused single chain molecule.

Methods of making these fragments are known in the art. (See for example, Harlow and Lane, *Antibodies: A Laboratory Manual*, Cold Spring Harbor Laboratory, New York  
5 (1988), incorporated herein by reference).

As used in this invention, the term "epitope" means any antigenic determinant on an antigen to which the paratope of an antibody binds. Epitopic determinants usually consist of chemically active surface groupings of molecules such as amino acids or sugar side chains and usually have specific three dimensional structural characteristics, as well as  
10 specific charge characteristics.

Antibodies which bind to the hedgehog, N or C polypeptide of the invention can be prepared using an intact polypeptide or fragments containing small peptides of interest as the immunizing antigen. The polypeptide such as N or C, or fragments thereof used to immunize an animal can be derived from translated cDNA or chemical synthesis which  
15 can be conjugated to a carrier protein, if desired. Such commonly used carriers which are chemically coupled to the peptide include keyhole limpet hemocyanin (KLH), thyroglobulin, bovine serum albumin (BSA), and tetanus toxoid. The coupled peptide is then used to immunize the animal (e.g., a mouse, a rat, or a rabbit).

If desired, polyclonal or monoclonal antibodies can be further purified, for example, by  
20 binding to and elution from a matrix to which the polypeptide or a peptide to which the antibodies were raised is bound. Those of skill in the art will know of various techniques common in the immunology arts for purification and/or concentration of polyclonal antibodies, as well as monoclonal antibodies (See for example, Coligan, *et al.*, Unit 9, *Current Protocols in Immunology*, Wiley Interscience, 1991, incorporated by reference).

It is also possible to use the anti-idiotypic technology to produce monoclonal antibodies  
25 which mimic an epitope. For example, an anti-idiotypic monoclonal antibody made to

-30-

a first monoclonal antibody will have a binding domain in the hypervariable region which is the "image" of the epitope bound by the first monoclonal antibody.

Antibodies as described herein as having specificity for N polypeptide, *e.g.*, Ab1 (residues 83-160), are useful for specific identification of cells or tissues expressing the N fragment of hedgehog. Similarly, antibodies described herein as having specificity for C polypeptide, *e.g.*, Ab2 (residues 300-391), are useful for specific identification of cells or tissues expressing the C fragment of hedgehog. Both antibodies, naturally, will also detect native hedgehog polypeptide.

The N and C-specific antibodies of the invention are useful for purification of N and C polypeptide, respectively, especially using the antibodies' immobilized on solid phase. By contacting a sample with anti-N antibody, both N and native hedgehog polypeptides can be isolated. By next contacting the sample removed by anti-N antibodies, with anti-C antibodies, the native hedgehog polypeptide is removed, thus allowing purification of N polypeptide. In a similar manner, C polypeptide can be antibody purified from a sample.

Monoclonal antibodies of the invention are suited for use, for example, in immunoassays in which they can be utilized in liquid phase or bound to a solid phase carrier. In addition, the monoclonal antibodies in these immunoassays can be detectably labeled in various ways. Examples of types of immunoassays which can utilize monoclonal antibodies of the invention are competitive and non-competitive immunoassays in either a direct or indirect format. Examples of such immunoassays are the radioimmunoassay (RIA) and the sandwich (immunometric) assay. Detection of the antigens using the monoclonal antibodies of the invention can be done utilizing immunoassays which are run in either the forward, reverse, or simultaneous modes, including immunohistochemical assays on physiological samples. Those of skill in the art will know, or can readily discern, other immunoassay formats without undue experimentation.

-31-

The term "immunometric assay" or "sandwich immunoassay", includes simultaneous sandwich, forward sandwich and reverse sandwich immunoassays. These terms are well understood by those skilled in the art. Those of skill will also appreciate that antibodies according to the present invention will be useful in other variations and forms of assays which are presently known or which may be developed in the future. These are intended to be included within the scope of the present invention.

Monoclonal antibodies can be bound to many different carriers and used to detect the presence of N or C polypeptide. Examples of well-known carriers include glass, polystyrene, polypropylene, polyethylene, dextran, nylon, amylases, natural and modified celluloses, polyacrylamides, agaroses and magnetite. The nature of the carrier can be either soluble or insoluble for purposes of the invention. Those skilled in the art will know of other suitable carriers for binding monoclonal antibodies, or will be able to ascertain such using routine experimentation.

For purposes of the invention, N or C polypeptide may be detected by the monoclonal antibodies when present in biological fluids and tissues. Any sample containing a detectable amount of N or C can be used. A sample can be a liquid such as urine, saliva, cerebrospinal fluid, blood, serum and the like, or a solid or semi-solid such as tissues, feces, and the like, or, alternatively, a solid tissue such as those commonly used in histological diagnosis. C polypeptide in particular is detectable in biological samples, since it tends to diffuse more readily than N polypeptide.

In performing the assays it may be desirable to include certain "blockers" in the incubation medium (usually added with the labeled soluble antibody). The "blockers" are added to assure that non-specific proteins, proteases, or anti-heterophilic immunoglobulins to anti-C or N immunoglobulins present in the experimental sample do not cross-link or destroy the antibodies on the solid phase support, or the radiolabeled indicator antibody, to yield false positive or false negative results. The selection of

-32-

"blockers" therefore may add substantially to the specificity of the assays described in the present invention.

The invention also provides a method for modulating proliferation or differentiation of neuronal cells comprising contacting the cells with a hedgehog polypeptide. The  
5 hedgehog polypeptide may be a native hedgehog polypeptide, or a N or C polypeptide, or functional fragments thereof. Preferably, the modulation is induction of proliferation or differentiation of a particular cell type. This can involve either synergistic positive induction of neuronal cells by N, or negative modulation by delta N-C for example (Lai,  
10 *et al.*, *Development* 121:2349, 1995). Delta N-C enhances expression of posterior relative to anterior neural genes and does so through inhibition of N (see EXAMPLE 18 and Figure 18D). In addition to hedgehog polypeptide, a TGF- $\beta$  factor may also be utilized in the method of the invention.

Previous studies with the rat hedgehog gene showed that co-culture of cells expressing rat hedgehog precursor gene, with explant from neural tube, was sufficient to induce  
15 formation of motor neurons and floor plate from the explant (Jessesl, T., and Dodd, J., In *Cell-Cell Signaling in Vertebrate Development* (ed. E.J. Robertson, *et al.*, pp 139-155, San Diego, Ca.), 1993). Therefore, based on the Examples herein showing that hedgehog is expressed near the floorplate of the ventral midline of the neural tube and notochord, neuronal cells substantially derived from floor plate neuronal cells can be induced by  
20 contacting the cells with hedgehog, N or C polypeptide. As used herein, the term "substantially derived", refers to those cells from the floor plate or proximate to the floor plate. For example, such cells include motor neurons and dopaminergic neurons. Those of skill in the art will be able to identify other neuronal cells substantially derived from the floor plate. Preferably the cells are vertebrate cells and most preferably, human cells.

25 In addition, as described herein in the Examples, hedgehog, and particularly C fragment, induces the expression of pituitary genes. Hedgehog is also effective in inducing anterior brain gene expression as exemplified by the OTX-A marker. Further, the addition of a

-33-

TGF- $\beta$  family member, for example activin, may be used to further induce expression of such genes. Other TGF- $\beta$  family members will be known to those of skill in the art. This apparent synergy of *hh* fragments with TGF- $\beta$  family members occurs through the TGF- $\beta$  protein inducing expression of neural inducers such as noggin and follistatin. The *hh* fragment then synergizes with these inducers to pattern neural gene expression.

*hh* fragments may also be useful as nerve-sparing agents or in restoring or promoting appropriate patterning during the healing of major limb trauma. In addition, the N and C fragments may be useful in the area of genetic counseling. Specifically, familial midline defects such as cyclopia, polydactyly or neural tube defects may be diagnosed by mapping close to *hh*. Since autoproteolytic defects may be responsible for the disorders, N or C therapy could be provided.

The invention also provides an autoproteolytic fusion protein comprising a first polypeptide including the proteolytic domain of the C polypeptide of the invention, a cleavage site recognized by the first polypeptide, and a second polypeptide. (It is understood that the first and second polypeptides can be reversed.) The auto-proteolytic activity of the native hedgehog protein is found entirely within the C polypeptide, therefore, the C polypeptide is useful for producing a fusion polypeptide which can then be cleaved at the junction of the C polypeptide and the second polypeptide. The fusion protein may optionally have a purification tag, such as a poly-histidine tag for isolation on a nickel column, or an antibody epitope tag, preferably on the C fragment. The cleavage site includes the sequence "GCF", which is recognized by the proteolytic domain of the C polypeptide and is utilized to cleave the second polypeptide from the C fragment. Also included in the invention is a polynucleotide encoding the fusion protein of the invention.

The invention also provides a method for producing an autoproteolytic fusion protein comprising operably linking a first polynucleotide, wherein the first polynucleotide encodes a first polypeptide including the proteolytic domain of the C polypeptide of the

-34-

invention and the cleavage site recognized by the proteolytic domain, and a second polynucleotide encoding a second polypeptide. As described above, the fusion protein may also include a carrier peptide and/or a purification tag.

5 The C polypeptide or functional fragment thereof is useful as a fusion partner to cause lipophilic modification and tethering of other proteins *in vivo* or *in vitro*. Such fusion proteins may be desirable for factors whose activity is required in a localized manner, either by targeting DNA constructs to specific cells or by introducing cells transfected with specific DNA constructs, for example. It may be desirable to lipid-modify a normally secreted protein in order to produce a cell-associated protein. For example, it  
10 may be desirable to produce a viral antigen that remains cell associated.

Alternatively, the C polypeptide or functional fragments thereof can be used as a fusion partner with a protein of interest (*e.g.*, Protein X fused to hh-C domain). Such fusions form thioesters at the junction between Protein X and hh-C (via an S to N shift). The thioesters are then available as substrates for a peptide ligation reaction in which any  
15 peptide or protein having an amino terminal cysteine (Peptide Y) is added and undergoes spontaneous rearrangement (S to N shift) that generates a stable peptide bond between Protein X and Peptide Y (Protein X-peptide bond-Peptide Y). For example, a protein that is toxic when produced *in vivo* could be produced *in vitro* using the hh-C domain fusion protein method.

20 The fusion polypeptide may also include an optional carrier peptide. The "carrier peptide", or signal sequence, is located at the amino terminal end of the fusion peptide sequence. In the case of eukaryotes, the carrier peptide is believed to function to transport the fusion polypeptide across the endoplasmic reticulum. The secretory protein is then transported through the Golgi apparatus, into secretory vesicles and into the  
25 extracellular space or, preferably, the external environment. Carrier peptides which can be utilized according to the invention include pre-pro peptides which contain a proteolytic enzyme recognition site. Acceptable carrier peptides include the amino terminal pro-

-35-

region of calcitonin or other hormones, which undergo cleavage at the flanking dibasic sites. However, it should be noted that the invention is not limited to the use of any particular peptide as a carrier. Other carrier peptides are known to those skilled in the art or can be readily ascertained without undue experimentation.

5 In one embodiment of the invention, a carrier peptide which is a signal sequence is included in the expression vector, specifically located adjacent to the N-terminal end of the fusion polypeptide. This signal sequence allows the fusion protein to be directed toward the endoplasmic reticulum. Typically, the signal sequence consists of a leader of from about 16 to about 29 amino acids, starting with two or three polar residues and  
10 continuing with a high content of hydrophobic amino acids; there is otherwise no detectable conservation of sequence known. Such signal sequences are known to those of skill in the art, and include the naturally occurring signal sequence derived from a hedgehog protein.

The fusion polypeptide of the invention includes a polypeptide encoded by a structural  
15 gene, preferably at the amino-terminus of the fusion polypeptide. Any structural gene is expressed in conjunction with the C-polypeptide (polynucleotide) and optionally a carrier peptide. The structural gene is operably linked with the carrier in an expression vector so that the fusion polypeptide is expressed as a single unit.

The identification of the autoproteolysis of hedgehog into the N and C domains is useful  
20 in a screening method to identify compounds or compositions which affect this processing activity. Thus, in another embodiment, the invention provides a method for identifying a composition which affects hh processing, which can be determined by activity or gene expression, comprising incubating the components, which include the composition to be tested (*e.g.*, a drug, a small molecule, a protein) and a hh polypeptide  
25 or a recombinant cell expressing hedgehog or a gene encoding a C domain or functional fragment thereof operably linked to an N domain or functional fragment thereof, under conditions sufficient to allow the components to interact, then subsequently measuring

the effect the composition has on hedgehog activity or expression. Fragments of hedgehog polypeptide or polynucleotide can be used in the method of the invention as long as autoproteolytic activity remains (*e.g.*, the construct exemplified in Figure 12a and 12b, Example 10). The observed effect on hh may be either inhibitory or stimulatory. For  
5 example, one can determine whether the N domain is associated with the cell, or whether the N domain is secreted into the medium, in other words, whether incomplete processing has occurred. Such methods for determining the effect of the compound or composition on hh processing include those described herein (see Example 10, Figure 12a and 12b) such as time course of autoproteolytic cleavage or course of cleavage based on  
10 concentration ranges. Alternatively, the effect of the composition on hh can be determined by the expression of anterior or posterior neural markers. Other methods for determining the effect of a composition on processing of N and C will be known to those of skill in the art. Various labels can be used to detect the N and C domains, for example, a radioisotope, a fluorescent compound, a bioluminescent compound, a chemiluminescent  
15 compound, a metal chelator or an enzyme could be used. Those of ordinary skill in the art will know of other suitable labels or will be able to ascertain such, using routine experimentation.

As used herein, "hh activity" as described in the screening method refers preferably to autoproteolytic activity. However, it is understood, that one of skill in the art could use  
20 the above-described screening assay to identify a composition having an affect on other hh activities, for example, zinc hydrolase activity. Appropriate assays for determining the effect on such activities will be known to those of skill in the art.

The following examples are intended to illustrate but not limit the invention. While they are typical of those that might be used, other procedures known to those skilled in the art  
25 may alternatively be used.

-37-

**EXAMPLE 1**  
**HEDGEHOG PROTEIN PROCESSING**

The full length form of the *hh* protein (F) migrates with a mobility corresponding to a relative molecular mass of 46 kD. FIGURES 1 (A) and (C) are immunoblots with  
5 antibodies against amino- (Ab1) and carboxy-terminal (Ab2) epitopes. GST fusion proteins containing either residues 83 to 160 or 300 to 391 from HH protein were expressed in *Escherichia coli*, purified as recommended [F. M. Ausubel, *et al.*, *Current Protocols in Molecular Biology* (Greene and Wiley-Interscience, New York, 1991)], and used to immunize rabbits by standard methods. The antibodies were affinity purified on  
10 a column of His<sub>6</sub>-U protein [E. Harlow and D. Lane, *Antibodies: A Laboratory Manual* (Cold Spring Harbor Laboratory, Cold Spring Harbor, NY, 1988)] linked to Affi-Gel 10 beads (Bio-Rad). The purification was performed as described (Harlow and Lane, *supra*) except that the acid and base elutions contained 10 percent dioxane. Biotinylated *hh* antibodies were prepared by purifying the rabbit antisera over a protein A column,  
15 followed by biotinylation with the use of the Immunoprobe biotinylation kit (Sigma). Immunoprecipitations were performed as described [Harlow and Lane] with the use of cold RIPA lysis buffer containing 0.25 mM phenylmethylsulfonyl fluoride (PMSF) and 5 mM EDTA for tissue homogenization. Lysates were precleared twice with pre-immune rabbit serum plus protein A beads (Gibco-BRL). Affinity-purified antibodies or  
20 preimmune serum was then added, and the immunoprecipitation was performed with protein A beads, with the use of NP-40 lysis buffer for the washes.

Immunoblots were performed with affinity purified Ab1 or Ab2 by either of two chemiluminescence based protocols. In the first protocol (used in Figures 1, 3, and 5) samples were resolved on 15 percent or 12 percent SDS-polyacrylamide gels (F. M.  
25 Ausubel *et al.*, *supra*) and transferred to Magnagraph nylon membranes (MSI) by electroblotting. Blots were developed with the use of an alkaline phosphatase conjugated donkey anti-rabbit IgG secondary antibody and Lumi-Phos 530 (Boehringer Mannheim) under recommended conditions. In the second protocol (used in FIGURE 8), samples

-38-

were transferred to nitrocellulose filters (Schleicher and Schuell), and blots were developed using ECL reagents (Amersham) as recommended. The secondary antibody in this case was horseradish peroxidase conjugated goat anti-rabbit IgG (Jackson ImmunoResearch). Lanes contain protein from induced untransfected S2 cells (lanes 1 and 13), transfected S2 cells induced to express *hh* (lanes 2 and 14), imaginal discs (lanes 3 and 15), wild type embryos (lanes 6 and 18), and *in vitro* translations of synthetic h mRNA both in the presence (lanes 5 and 17) and absence of microsomes (lanes 4 and 16).

cDNAs encoding various *hh* protein species were cloned into the pMK33 vector, which allows for inducible expression under metallothionein promoter control (M. R. Koelle et al., *Cell* 67:59,1991). Stable S2 cell lines were made by transfection of the *hh*/pMK33 plasmids with constant selection for hygromycin resistance. Proteins were expressed by plating a log phase culture of cells diluted to 0.1 A<sub>595</sub> units, waiting 48 hours, inducing with CuSO<sub>4</sub> at 0.2 mM final concentration, and harvesting the cells and/or supernatant 24 hours later. Cell samples for immunoblotting were made by adding 10 volumes of 1X SDS PAGE loading buffer to pelleted cells.

*In vitro* translations were performed with the use of the TNT coupled transcription-translation system (Promega). <sup>35</sup>S methionine (DuPont NEN) was used for detection by autoradiography. In the heparin binding experiment *in vitro* translation lysate with microsomes that produce wild-type *hh* protein was added to heparin agarose (Sigma) or Sepharose CL-4B (Pharmacia) beads pre-equilibrated with heparin binding buffer (HBB; 20 mM Tris (7.4), 150 mM NaCl, 0.1 percent Triton X-100). Samples were incubated at 4° C for four hours with gentle rocking. After pelleting the beads, supernatants in some samples were analyzed (lanes 2 and 4). The beads were then washed 5 times with chilled HBB and samples (lanes 3 and 5) were subsequently eluted at 80° C for 10 minutes in SDS PAGE loading buffer (F. M. Ausubel et al., *supra*).

Embryos from the wild-type Canton-S line and from the matings, *hshh/hshh* or *hshh* H329A/*hshh* H329A X y, *Sco*/CyO, *enlacZ11::wg* (Kassis, et al., *Proc. Natl. Acad. Sci.*

U.S.A. 89: 1919, 1992), were collected 0 to 16 hours after egg laying (AEL) at 25° C. They were heat shocked for 30 minutes at 37° C and allowed to recover for 1 hour at 25° C. Embryos in FIGURE 1 (Canton-S) were collected 4 to 8 hours AEL at 25° C. In preparation for immunoblotting, all embryos were dechorionated in 2.6 percent sodium hypochlorite and homogenized in 10 volumes of 1X SDS PAGE loading buffer.

Multiple species were detected and minor cross reactive bands are seen in most samples including extracts of induced untransfected S2 cells (lanes 1 and 13). One of these bands (occurring in both panels) co-migrates with U (at 39 kD) and is particularly abundant in lane 6 of FIGURE 1 (A).

FIGURES 1 (B) and (D) are blots of samples immunoprecipitated with Ab1 (B, lanes 7-9), Ab2 (D, lanes 19-21), or pre-immune serum (B, lanes 10-12 and D, lanes 22-24). Detection was with biotinylated derivatives of Ab1 (B) and Ab2 (D). Samples used were: induced untransfected S2 cells, lanes 7, 10, 19 and 22; transfected S2 cells induced to express *hh*, lanes 8, 11, 20 and 23; and embryos, lanes 9, 12, 21 and 24. For either antibody, *hh* protein fragments were specifically immunoprecipitated from *hh* expressing cells and embryos, but not from untransfected cells. (E) In the schematic diagram, cleavage sites are denoted by arrows. The cleavage site marked by the asterisk is inferred by identification of only one cleavage product and may therefore occur at another location within the C fragment. The first two columns to the right of the diagram indicate the reactivity of Ab1 and Ab2 to each *hh* fragment. The other columns indicate the presence (+) or absence (-) of each *hh* fragment in the various samples. Parentheses around F and N<sub>ss</sub> indicate that these species are detected in *in vitro* translation reactions but not *in vivo*.

The 46kD species was detected from *in vitro* translation extracts by Ab1 and Ab2 (FIGURE 1, lanes 4 and 16), and was partially converted to a species of 39 kD (U) when translation occurred in the presence of microsomes (FIGURE 1, lanes 5 and 17). A 39 kD species co-migrating with U is also present in extracts from all *in vivo* sources, but

-40-

none of these extracts contain detectable levels of F. U represents the signal-cleaved form of F; signal cleavage thus appears to be relatively inefficient *in vitro*, as reported previously, (J. J. Lee, *et al.*, *Cell*, 71:33, 1992), but is highly efficient *in vivo*. To confirm that signal cleavage indeed is occurring at this unusual internal location, a mutation that changes residue S<sub>84</sub> to N at the predicted signal cleavage site was introduced. This mutation prevented conversion by microsomes of F to U and also produced a species that comigrated with F upon transfection into cultured S2 cells. The effects of independently mutating the two methionine codons present upstream of the signal sequence were also examined. *In vitro* translation of the sequence in which the first methionine is removed produces a protein species intermediate in mobility between F and U, and this species is converted to a species that comigrates with U in the presence of microsomes or when produced *in vivo*. Alteration of the second methionine codon caused no change in the electrophoretic mobility of *Hh* protein produced *in vivo* or *in vitro*.

Smaller species of *Hh* proteins from *in vivo* sources have been reported previously (T. Tabata and T. B. Kornberg, *Cell* 76: 89, 1994). The latter study examined not endogenous proteins, but proteins induced to express at high levels from exogenously introduced constructs. The antibody used did not distinguish epitopes from distinct portions of the molecule.

In addition to signal cleavage, a further cleavage of the U precursor is responsible for generating other forms of *hh* protein observed *in vivo*. This was deduced from the observation that Ab1 and Ab2 both detected the U (uncleaved) species, but also interacted individually with smaller protein species expressed endogenously in embryos and imaginal discs or with species expressed upon introduction of the *hh* gene into S2 cells. Ab1 thus interacts with a 19kD species from all of these tissues (FIGURE 1, lanes 2, 3, 6, 8, 9), while Ab2 interacts with a 25 kD species and a 16 kD species (FIGURE 1, lanes 14, 15, 18, 20, 21). The 19 kD species hereafter is referred to as N (N-terminal fragment), the 25 kD species as C (C-terminal fragment) and the 16 kD species as C<sup>\*</sup>; these species represent the major forms of endogenous *hh* protein present *in vivo*.

-41-

The proposed cleavages by which these species arise are shown schematically in the bottom portion of FIGURE 1. The N and C species are uniquely detected by Ab1 and Ab2, respectively, and the sum of the relative masses of the two smaller species is roughly equivalent to the relative mass of U. The electrophoretic mobilities of the F and U species are somewhat at variance with their predicted relative masses (52.1 kD and 43.3 kD, respectively). The identities of these species were confirmed by *in vitro* translation of a variety of *hedgehog* open reading frames modified to contain different extents of sequence at the NH<sub>2</sub>- or COOH- terminus, and by insertion of epitope tags. The migration anomalies appear to be associated with protein species in which sequences from both the NH<sub>2</sub>- and COOH-terminal fragments are simultaneously present. The mobilities of the NH<sub>2</sub>- and COOH-terminal fragments, in contrast, correspond to relative masses (19 kD and 25 kD, respectively) that sum to yield 44 kD, roughly equivalent to the expected relative mass of U.

A simple mechanism that could account for the derivation of the two smaller species therefore would be a single internal cleavage of the U precursor. Processing of the *hh* protein when translated *in vitro* also yields a 25 kD species (C; lanes 16 and 17) and either a 29 kD or 19 kD (N) species (lanes 4 and 5). The 19 kD species comigrates with N, and its formation depends upon the presence of microsomes, consistent with the proposal that N derives from F by signal cleavage and a further internal cleavage. The overall pathway for formation of the predominant forms of *hh* protein observed *in vivo* thus appears to involve signal cleavage of F to generate U. U is then cleaved internally to form N and C, which are the predominant forms found *in vivo*. Further processing of the 25 kD C species might then generate the 16 kD C\* species, but whether this processing is a single cleavage event or not is not clear since Ab2 does not recognize the smaller 9 kD fragment that would result. The processing of C to generate C\* appears to occur with greater efficiency in imaginal discs as compared to embryos (compare lanes 15 and 18); this may be caused by the more extended mass isolation procedure of imaginal discs (O. M. Eugene, *et al.*, *Tissue Culture Assn. Man.*, 5: 1055, 1979).

## **EXAMPLE 2**

### **AUTO-PROTEOLYSIS OF THE HEDGEHOG PROTEIN**

The comigration of endogenous and *in vitro*-generated *hh* protein species suggested that *in vitro* processing is similar to that observed *in vivo*. FIGURE 2 shows limited sequence similarity between *hh* proteins and serine proteinases. *hh* protein sequences are aligned to residues 323 to 329 of the *D. melanogaster* protein and numbered as positions 1 to 7 (group A). Conserved *hh* residues are in bold letters. The catalytic histidines (A. J. Barrett, in *Proteinase inhibitors* A. J. Barrett, G. Salvesen, Eds. (Elsevier, Amsterdam, 1986) pp. 3-22) of mammalian serine proteinases (group B) are aligned to the invariant histidine at position 7 in *Hh* proteins. Abbreviations are as follows: C-*Shh*, chicken *Sonic hh* (R. D. Riddle, *et al.*, *Cell* **75**: 1401, 1993); M-*Shh*, mouse *Sonic hh* (Y. Echelard *et al.*, *Cell* **75**: 1417, 1993) (identical to *Hhg*-1; R *vhh*-1, rat *vhh*-1 (H. Roelink *et al.*, *Cell* **76**: 761, 1994); Z-*Shh*, zebrafish *Sonic hh* (S. Krauss, *et al.*, *Cell* **75**: 1431, 1993) (identical to *shh*) and zebrafish *vhh*-1, (H. Roelink *et al.*, *supra*); *twhh*, no other abbreviation; M-*Dhh*, mouse *Desert hh* (Y. Echelard *et al.*, *Cell* **75**: 1417, 1993); M-*Ihh*, mouse *Indian hh* (Y. Echelard *et al.*, *supra*); CHT, bovine chymotrypsin; TRP, bovine trypsin; ELA, porcine elastase; UKH, human urokinase; C1R, human complement factor 1R; C1S, human complement factor 1S; MCP, rat mast cell protease; FAX, human blood clotting factor X; TPA, human tissue plasminogen activator.

Figure 2 shows that a seven residue region of *hh* coding sequence (residues 323 to 329 in the *Drosophila* protein) displays some similarity to the sequences of serine proteases. This region lies approximately two thirds of the distance from the signal cleavage site to the carboxy-terminus, and includes Thr and His, residues (positions 4 and 7 in FIGURE 2) that are invariant among all *hh* sequences from all species. In the serine proteases, this conserved sequence contains an invariant His that acts as a general base in catalysis (A. J. Barrett, in *Proteinase inhibitors* A. J. Barrett, G. Salvesen, Eds. Elsevier, Amsterdam, 1986, pp. 3-22).

To determine whether this invariant His residue in the *hh* protein indeed plays a role in auto-proteolysis, two proteins from *E. coli* were purified: one carried the wild type sequence and the other a substitution of an Ala codon for the His codon at position 329 (H329A). Both of these proteins were engineered to contain a hexa-histidine tag at the amino terminus fused to *Drosophila* sequences extending from a residue just before the signal cleavage site to the carboxy-terminus (residues 83 to 471; the wild type form of this protein is referred to as His<sub>6</sub>-U). Both proteins were extensively purified under denaturing conditions using a Ni<sup>++</sup> -chelating matrix. FIGURE 3(A) is a coomassie blue stained polyacrylamide gel that shows the production and purification of His<sub>6</sub>-U and His<sub>6</sub>-U<sub>H329A</sub> proteins from *E. coli*. Samples were molecular weight markers (lanes 1 and 2); lysates of *E. coli* cells carrying the His<sub>6</sub>-U expression construct without (lane 3) and with (lane 4) induction by IPTG; purified His<sub>6</sub>-U protein (lane 5); lysates of *E. coli* cells that carry the His<sub>6</sub>-U<sub>H329A</sub> expression construct without (lane 6) and with (lane 7) induction by IPTG; purified His<sub>6</sub>-U<sub>H329A</sub> protein (lane 8). Purified proteins were essentially homogeneous except for several minor species of lower relative mass; these species are endogenous breakdown products of the full-length proteins since they were absent in uninduced extracts and were detectable with *hh* antibodies. FIGURE 3 (B) is an immunoblot detected with Ab2 showing transfected S2 cells induced to express *hh* (lane 1); His<sub>6</sub>-U and His<sub>6</sub>-U<sub>H329A</sub> proteins incubated in cleavage reaction buffer for 0 hours (lanes 2 and 5), for 20 hours (lanes 3 and 6), and for 20 hours in the presence of 20 mM TAME (a serine protease inhibitor) (lanes 4 and 7). Upon incubation the His<sub>6</sub>-U, but not the His<sub>6</sub>-U<sub>H329A</sub> protein, released a fragment presumed to be C on the basis of reactivity with Ab2 and co-migration with C produced in S2 cells. Release of C (lane 3) was only partially inhibited by TAME.

Preliminary proteinase inhibitor studies have been performed on *in vitro* translated *Hh* protein by adding various inhibitors at the start of the translation reaction. These studies have been complicated by the fact that numerous protease inhibitors lower or block translation efficiency. In some cases the effectiveness of an inhibitor was assayed by determining if addition of an inhibitor to a completed translation reaction will inhibit the

self-processing that normally continues to occur. At this time we can only state the following with certainty: (i) the serine protease inhibitor TAME (p-toluenesulfonyl-L-arginine methyl ester) inhibits auto-proteolysis of in-vitro translated *Hh* protein; (ii) soybean trypsin inhibitor,  $\alpha_1$  anti-trypsin, aprotinin, leupeptin, and E-64  
5 do not block auto-proteolysis of translated *Hh* protein; and (iii) TAME partially inhibits auto-proteolysis of purified His<sub>6</sub>-U protein (FIGURE 3, panel B).

As seen in FIGURE 3B, upon dilution of denaturant the wild type protein but not the H329A mutant protein released a 25 kD species detectable by Ab2 and identical in mobility with the C species produced from *in vitro* translations and various *in vivo*  
10 sources. This cleavage was also observed when the wild type protein was purified and renatured by other protocols and cleaved under distinct conditions. Plasmids encoding the His<sub>6</sub>-U and His<sub>6</sub>-U<sub>H329A</sub> proteins were generated by inserting sequences corresponding to residues 83 to 471 from the wild-type or *hh* H329A ORF into the pRSETB expression vector (Invitrogen). Proteins were induced in BL21(DE3)/pLysS *E. coli* cells as described  
15 (F. M. Ausubel et al., *supra*). The basic purification was performed on Ni-NTA agarose beads (Qiagen) by a denaturing protocol with the use of 6 M guanidinium HCl and 8 M urea essentially as recommended (a detailed protocol of exact conditions used is available upon request). Washes contained 0.2 percent Tween 20 and 5 mM  $\beta$ -mercaptoethanol. The final wash buffer was: 6 M urea, 100 mM Tris, 500 mM NaCl, 20 percent glycerol,  
20 (pH 7.4). Elutions were with the final wash buffer containing 250 mM imidazole. In vitro cleavage reactions were performed by incubating the purified protein (diluted 1:30 in the final mix) in cleavage buffer [50 mM Tris, 500 mM NaCl, 5 percent glycerol, 0.2% Triton X-100, 50 mM DTT, (pH 7.4)]. To isolate soluble full-length His<sub>6</sub>-U protein free from denaturants or detergents, additional steps were taken (this refers to the other renaturation  
25 protocols mentioned in the text). Full-length protein from the eluate described above was further purified from breakdown products by precipitation, by urea removal through dialysis. The precipitate was then re-solubilized in a buffer containing guanidinium HCl and loaded onto another Ni-NTA agarose column. After washing as described, the protein was re-folded (while attached to the beads) by gradual dilution of urea (from 6M to 0.5M)

-45-

with dilution buffer [(100 mM Tris, 500 mM NaCl, 20 percent glycerol, (pH 7.4)] over an 8 hour period at 4° C. The protein was eluted with dilution buffer containing 250 mM imidazole and 0.5M urea. The eluate was dialyzed in 100 mM Tris, 150 mM NaCl, 10 percent glycerol, (pH 7.4) at 4° C and stored at -70° C.

### EXAMPLE 3

#### MAPPING THE AUTO-PROTEOLYTIC FUNCTIONS OF *hh*

To more precisely define the domain of the *hh* protein responsible for this auto-proteolytic event, the effects of several distinct types of mutations upon *in vitro* processing were examined. The most informative mutation was a deletion that removes residues 89 to 254 ( $\Delta$ 89-254), which together constitute most of the amino acids within the portion of the molecule presumed to form the N fragment. *In vitro* translations of wild-type and mutant *Hh* proteins from *Drosophila* (FIGURES 4 A-C) and zebrafish (FIGURE 4D) are shown. The locations of mutations and cleavage sites (arrows) in these proteins are schematically illustrated (FIGURE 4E). In the *Drosophila* protein (FIGURES 4A, B, and C), auto-proteolysis is blocked or severely inhibited by several mutations in the COOH-terminus (H329A, 294 trunc, 410 trunc, flu408 and 456 trunc), but is unaffected by a large deletion ( $\Delta$ 89-254) or insertion of a flu-tag epitope trimer (flu227) in the NH<sub>2</sub>-terminus. Auto-proteolysis thus depends primarily on residues within the C fragment (sequences to the right of the cleavage site in the diagram below; see FIGURE 1). Furthermore, the H329A/flu227 double mutant is not cleaved by wild-type protein in a mixing experiment (lane 11), suggesting an intramolecular mechanism for auto--proteolysis. *Hh* proteins encoded by the zebrafish genes *twhh* and *shh* display a pattern of processing (D) similar to that of the *Drosophila* protein although the NH<sub>2</sub>-terminal fragment of each zebrafish protein (23 kD for *twhh* and 22 kD for *shh*) has a lower apparent mass than the COOH-terminal fragment (25 kD for *twhh* and *shh*). This is the result of a shorter stretch of residues that precedes the signal sequences as compared to the *Drosophila* protein. Processing is blocked by H273A and H270A mutations in *twhh*

-46-

and *shh* proteins respectively (analogous to the H329A mutation in the *Drosophila* protein), which suggests an auto-proteolytic processing mechanism is used similar to that observed for the *Drosophila* protein.

5 *In vitro* translations were performed with the use of the TNT coupled transcription-translation system (Promega). <sup>35</sup>S methionine (DuPont NEN) was used for detection by autoradiography. In the heparin binding experiment (FIGURE 8C), *in vitro* translation lysate with microsomes that produce wild-type *Hh* protein was added to heparin agarose (Sigma) or Sepharose CL-4B (Pharmacia) beads pre-equilibrated with heparin binding buffer (HBB; 20 mM Tris (7.4), 150 mM NaCl, 0.1 percent Triton  
10 X-100). Samples were incubated at 4° C for four hours with gentle rocking. After pelleting the beads, supernatants in some samples were analyzed (lanes 2 and 4). The beads were then washed 5 times with chilled HBB and samples (lanes 3 and 5) were subsequently eluted at 80° C for 10 minutes in SDS PAGE loading buffer (F. M. Ausubel et al., *supra*).

15 All mutations in the *hh* gene were generated in the plasmid pF1 (J. J. Lee, *et al.*, *supra*). Mutations in the zebrafish *twhh* and *shh* genes were generated with the original cDNA clones as described (Ekker, *et al.*, *Current Biology*, 5(8): 944,1995). All point mutations were generated with the use of recombinant circle PCR (D. H. Jones and S. C. Winistorfer, *Biotechniques* 12: 528, 1992). The flu408 and flu227 mutations were  
20 generated by inserting a trimer of the influenza hemagglutinin antigen (42 residues for flu408 and 43 residues for flu227) into the AlwN I and Bgl I sites present in the *hh* ORF (nucleotide positions 1604 and 1058 respectively) (J. J. Lee, *et al.*, *supra*). The Δ89-254 mutation was generated by removing sequences between the EcoN I site (644) and the Pml I site (1145). The 294 trunc mutation was generated by removing sequences between  
25 the Acc I site (1265) and the Xcm I site (1792). The 410 trunc mutation was previously generated and identified as *Hh*<sub>410</sub> (J. J. Lee, *et al.*, *supra*). To map the mutation in the *hh*<sup>13E</sup> allele (base change C<sub>1756</sub> to A; coding change Ty<sub>457</sub> to STOP), DNA isolated from *hh*<sup>13E</sup>/TM3 was used to seed PCR reactions generating regions of the *hh* ORF and flanking

-47-

sequences, which were subcloned into Bluescript KSM (Stratagene). Six clones each, derived from two different PCR amplifications were sequenced.

As seen in lanes 1 and 2 of FIGURE 4A, this construct generates a full length species of a mobility corresponding to the expected relative mass of 33 kD, and two cleaved products whose apparent relative masses (25 and 9 kD) sum to give the relative mass of the larger species. The smaller of the cleaved products will occasionally migrate as two bands as seen in Fig 4A. We have chosen the lower of the two bands between the 14.3-kD and 6.2-kD markers for our molecular weight measurement. The larger of the two cleaved products comigrates with the C species produced from the wild type protein, suggesting that the  $\Delta 89-254$  *hh* protein contains the residues normally present in C and all of the determinants required for auto-proteolysis, including the normal cleavage site; most of the residues within N are dispensable for auto-proteolytic activity.

In contrast, lesions affecting residues presumed to lie within C block auto-proteolysis *in vitro*. All mutations tested by *in vitro* translation were also examined in S2 cells by immunoblotting. In all cases the patterns of cleavage in S2 cells were identical to those observed in translations except that C\* was always present whenever C was formed. The former fragment was not observed in translations. These include the H329A mutation described above, a mutation that inserts an influenza virus epitope between residues 408 and 409 (flu408), and three mutations that cause premature termination of the protein at the carboxy terminus. The two most severe truncations, 294 trunc and 410 trunc, are mutations generated *in vitro*. They cause a loss of 177 and 61 residues, respectively, from the carboxyl-terminus of the protein, and neither undergoes proteolysis. The 456 trunc *hh* protein is like that encoded by the EMS-induced *hh*<sup>13E</sup> mutant allele, which results in the loss of 15 residues from the carboxy-terminus of the protein. This protein undergoes auto-proteolysis, as demonstrated by the appearance of a 24 kD band in place of C, but the efficiency of the reaction is much impaired *in vitro* (FIGURE 4B). Auto-proteolysis of the *hh* protein relies mainly upon residues within C; deletion or alteration of residues

within this domain is associated with reduced efficiency of processing, and one such deletion appears to be the cause of the *hh*<sup>13E</sup> mutation.

The sequence homology and auto-proteolytic function of the full length *hh* protein suggested the possibility that F or the C fragment is a sequence-specific protease. As a first step in clarifying the mechanism of auto-proteolysis, an influenza virus epitope tag was introduced into the N-terminus of a *hh* open reading frame that also carried a H329A mutation. FIGURE 4C shows that the insertion of the epitope tag alone does not interfere with auto-proteolysis (lane 9), and yields a normal C fragment and an N fragment of increased relative mass (compare to wild type in lane 12). The protein carrying both mutations does not undergo proteolysis (lane 10), and since the epitope-tagged N fragment migrates differently from N, this double mutant provides an ideal substrate to look for intermolecular cleavage upon mixture with a wild type sequence. Lane 11 shows that in such a mixture, although normal N is formed, no tagged N can be detected. Thus, in this experiment, no appreciable intermolecular cleavage occurs. We also failed to detect intermolecular cleavage in the following two experiments: (i) co-transfection of wild type and 410 trunc sequences into S2 cells (the cleaved 410 trunc protein would yield a smaller and therefore identifiable form of C); (ii) mixing of excess unlabelled, purified His<sub>6</sub>-U protein with labelled, *in vitro* translated H329A mutant protein. Thus, although an intermolecular mechanism for regulation of auto-proteolysis or for cleavage of other proteins can not be ruled out, the current evidence suggests that cleavage of the *hh* protein occurs predominantly by an intramolecular mechanism.

The *hh* gene has been broadly conserved in evolution, with single homologues unidentified in a wide variety of invertebrate species and multiple distinct homologues in each of several vertebrate species (Y. Echelard et al., *Cell* 75: 1417, 1993; S. Krauss, et al., *Cell* 75: 1431, 1993; H. Roelink et al., *Cell*, *supra*). As seen in FIGURE 2, all of these coding sequences contain an invariant histidine and other conserved residues at a position corresponding to H329 in the *Drosophila* protein. In addition, the protein encoded by at least one of the mouse genes appears to be processed *in vivo* to yield two

-49-

smaller species in a manner resembling the *in vivo* processing of the *Drosophila* protein. To determine whether auto-proteolysis may also play a role in vertebrates we examined the behavior of proteins encoded by two distinct *hh* homologues from the zebrafish, *twhh* and *shh*. FIGURE 4D demonstrates that when these sequences are translated *in vitro*, smaller species are generated whose relative masses sum to yield approximately the relative mass of the full length protein (lanes 1 and 3). As seen in lanes 2 and 4, this cleavage reaction is blocked by substitution of Ala codons for the His codons at positions corresponding to H329 in *Drosophila* (see FIGURE 2). Vertebrate *hh* proteins thus appear to be processed by a similar mechanism as the *Drosophila* protein.

#### EXAMPLE 4

#### ROLE OF AUTO-PROTEOLYSIS IN EMBRYOS

Numerous functions for the *hh* gene have been described in *Drosophila*. At the morphological level these include a role in patterning of larval cuticular structures and adult structures such as the eye and appendages (C. Nüsslein-Volhard and E. Wieschaus, *Nature* 287: 795, 1980; and J. Mohler, *Genetics* 120: 1061, 1988).; the mechanistic basis for these morphological effects involves signaling for maintenance or induction of gene expression in embryos and imaginal discs (J. J. Lee, *supra*; T. Tabata and T. B. Kornberg, *Cell* 76: 89, 1994; and K. Basler and G. Struhl, *Nature* 368: 208, 1994). To ascertain the importance of auto-proteolysis for these functions, the H329A mutant gene under control of the hsp 70 promoter was introduced by P element-mediated transformation into the *Drosophila* germline. The *hshh* H329A construct was made identically to the *hshh* construct with the use of a *hh* ORF fragment containing the H329A mutation. Transgenic flies were generated from a  $y^1 w^{1118}$  parental strain using standard methods of P element mediated transformation (A. C. Spradling and G. M. Rubin, *Science* 218: 341 1982). A line, HA3, carrying the *hshh* H329A P element on the second chromosome was maintained as a homozygous stock. To assay for expansion of *wg* stripes, embryos collected at 4 to 6 hours after egg laying (AEL) at 25° C were subjected to the following

heat shock protocols prior to fixation. Embryos receiving single shocks (10 or 30 minutes at 37° C) were allowed to recover for 1 hour at 25° C. Embryos receiving double shocks (two 10 minute or two 30 minute shocks at 37° C) were allowed to recover 90 minutes after the first shock and 40 minutes after the second (Both recoveries were at 25° C. The double 30 minute protocol was as previously described, (S. Krauss, *supra*). *In situ* hybridizations were performed as described (D. Tautz, *Chromosoma* 98: 81, 1989) using a *wg* specific probe (D. T. Chang et al., *supra*). Embryos assayed for cuticle phenotype were heat shocked 6 to 8 hours AEL for 30 minutes at 37° C, allowed to develop at 25° C for 36 hours and then processed and mounted as described (M. Ashburner, *Drosophila: A Laboratory Manual*, Cold Spring Harbor Laboratory Press, New York, 1989). Immunolocalizations (single or double stains) were performed as described. With the use of affinity purified Ab1 or Ab2 for the primary antibody and alkaline phosphatase (AP) or horseradish peroxidase (HRP) conjugated anti rabbit or mouse IgG (Jackson Immunoresearch) for the secondary. Embryos from a *hh*<sup>13E</sup>/TM3 *ftz-lacZ* (the balancer chromosome was from the Bloomington Stock Center, strain 3218) stock homozygous for the *hh*<sup>13E</sup> allele were identified by the lack of staining with an anti  $\beta$ -galactosidase antibody (Promega) in a double stain with Ab2 (FIGURE 9, panel D). Staining in FIGURE 9, panels B and C were performed formaldehyde fixed Canton-S embryos with the use of an AP conjugated anti-rabbit IgG secondary. Although standard formaldehyde fixation was generally used, heat and acid-formaldehyde fixation also gave similar results. GST fusion proteins containing either residues 83 to 160 or 300 to 391 from the *Hh* protein were expressed in *E. coli*, purified as recommended (F. M. Ausubel et al., *supra*), and used to immunize rabbits by standard methods. The antibodies were affinity purified on a column of His<sub>6</sub>-U protein (Harlow and Lane, *supra*) linked to Affi-Gel 10 beads (Bio-Rad). The purification was performed as described (Harlow and Lane, *supra*) except that the acid and base elutions contained 10 percent dioxane. Biotinylated *hh* antibodies were prepared by purifying the rabbit antisera over a protein A column, followed by biotinylation with the use of the Immunoprobe biotinylation kit (Sigma). Immunoprecipitations were performed as described (Harlow and Lane, *supra*) with the use of cold RIPA lysis buffer containing 0.25 mM PMSF and 5 mM EDTA for tissue

-51-

homogenization. Lysates were precleared twice with pre-immune rabbit serum plus protein A beads (Gibco BRL). Affinity purified antibodies or pre-immune serum was then added, and the immunoprecipitation was performed with protein A beads, with the use of NP-40 lysis buffer for the washes.

5      FIGURE 5 (A) and (B) are immunoblots developed with the use of Ab1 and Ab2 antibodies respectively. Lanes 1 and 6, induced untransfected S2 cells; lanes 2 and 7, transfected S2 cells induced to express *hh*; lanes 3 and 8, heat shocked wild-type embryos; lanes 4 and 9, heat shocked *hshh* embryos; lanes 5 and 10, heat shocked *hshh* H329A embryos. In heat shocked *hshh* embryos, the wild-type *Hh* protein is both induced and properly processed to generate the U, N, C and C\* species seen in other expression contexts. In contrast, the H329A is induced but not appreciably processed in *hshh* H329A embryos (the low levels of processed species in lanes 5 and 10 are probably from endogenous *hh* expression since they are seen at identical levels in heat shocked wild-type embryos in lanes 3 and 8).

15      FIGURE 5 shows that heat shock induction results in the formation of an abundant species that corresponds to U based on its mobility and its interaction with Ab1 and Ab2 (lanes 5 and 10). In contrast, induction of wild type *hh* protein using a similar construct resulted in similar levels of the N and C processed products (lanes 4 and 9), with very little uncleaved U. Thus, as observed *in vitro* and in S2 cells, the H329A mutation in embryos appears to greatly reduce the efficiency of auto-proteolytic cleavage of the *hh* protein.

25      In FIGURE 6, the embryonic distribution of *wingless* (*wg*) RNA as revealed by in situ hybridization is shown in FIGURE 6 (A) wild-type (homozygous *y<sup>1</sup> w<sup>1118</sup>*), (B) *hshh*, and (C) *hshh* H329A embryos that were exposed to two 10 minute heat shocks separated by a 90-minute recovery period. Wild-type embryos showed little change in *wg* expression, whereas the wild-type protein and, to a lesser extent, the H329A protein each induced ectopic *wg* expression (Table 1). Panels (D), (E), and (F) show the dorsal surfaces of *y<sup>1</sup>*

-52-

*w<sup>1118</sup>*, *hshh*, and *hshh* H329A larvae, respectively, at the level of the fourth abdominal segment. These larvae were shocked for 30 minutes as embryos and allowed to complete embryogenesis. Cuticle cell types (1°, 2°, 3°, and 4°) are labeled as described (J. Heemskerk and S. DiNardo, *Cell* 76: 449, 1994). Note the expansion of 2° cell types (naked cuticle) at the expense of 3° and some 4° types in the *hshh* embryo (E) under conditions where the phenotype of *hshh* H329A embryos (F) is identical to that of control embryos (D).

Perhaps the earliest known requirement for *Hh* protein is in maintenance of an adjacent stripe of *wingless* (*wg*) gene expression in each embryonic segment (A. Martinez Arias, *et al.*, *Development* 103: 157, 1988; and S. DiNardo, *et al.*, *Nature* 332: 604, 1988). This requirement is deduced from the loss of *wg* expression when *hh* function is absent; in addition, the ubiquitous expression of wild-type *Hh* protein induces expansion of the domain of *wg* gene expression (P. W. Ingham, *Nature* 366: 560, 1993). The effects of the H329A mutation upon *wg* expansion were examined by heat shocking embryos carrying the H329A mutant construct in parallel with embryos containing the wild-type construct. Although the H329A mutant protein is able to induce some expansion of the *wg* domain, the efficiency of this activity is impaired relative to that of the wild-type protein (FIGURE 6, B and C; Table 1). The difference in efficiency ranges nearly as high as threefold depending upon the heat shock regime, and these results suggest that a uto-proteolysis of the *Hh* protein is important for optimal activity in embryonic signaling to induce *wg* expression.

-53-

**TABLE 1****Wild-type and mutant *hh* activity in embryonic induction of *wg* expression\***

	minutes of heat shock			
	10	30	10/10	30/30
5 <i>hshh</i>	1.0 ± 0.3 (93)	1.5 ± 0.6 (120)	2.9 ± 0.3 (41)	2.8 ± 0.4 (54)
<i>hshh</i> H329A	0.7 ± 0.5 (190)	0.9 ± 0.4 (111)	1.1 ± 0.4 (145)	1.9 ± 0.5 (93)

\* Expansion of *wg* expression beyond wild-type controls is given as average number of cell diameters ± standard deviation with number of embryos scored in parentheses.

-54-

The effects of *Hh* protein on the patterning of cuticular structures are most clearly visible on the dorsal surface of the larva, where four distinctive cell types can be identified in each parasegment. These cell types have been designated 1°, 2°, 3°, and 4°, from anterior to posterior, with *hh* transcription occurring in precursors of the 1° cells (J. Heemskerk and S. DiNardo, *supra*). Differentiation of the first three cell types was shown to be dependent upon *hh* gene function, and it has been proposed that the fates of these cells are determined by the concentration of *Hh* protein, with highest concentrations producing the 1° fate, intermediate concentrations producing the 2° fate, and the lowest concentrations producing the 3° fate (J. Heemskerk and S. DiNardo, *supra*). This proposal was supported by observations that the most anterior cell types display the greatest sensitivity to a reduction of *hh* expression, and that all of the 3° and some of the 4° bristles are replaced by naked cuticle characteristic of the more anterior 2° cell type when *hh* is expressed ubiquitously at high levels. We have reproduced suppression 3° and some 4° fates by heat shock induction of embryos that carry our wild-type construct (FIGURE 6E), but find that the H329A mutant is unable to alter cell fates in the dorsal cuticle of the larva (FIGURE 6F). Auto-proteolysis, or perhaps some other function blocked by the H329A mutation, thus appears to be essential for the patterning influence of *Hh* protein upon the dorsal cuticle.

## **EXAMPLE 5**

### **EFFECTS OF THE H329A MUTATION UPON SIGNALING IN IMAGINAL DISCS**

Studies of H329A mutant protein were extended to the function to the patterning of adult structures and signaling within imaginal discs. In the eye imaginal disc *hh* function is required for appropriate development of pattern (J. Mohler, *Genetics* 120: 1061, 1988; J. J. Lee, *supra*; and J. Mohler and K. Vani, *supra*) and more recently has been shown to control progression of a wave of differentiation via induction of *decapentaplegic* (*dpp*)

gene expression in the morphogenetic furrow of the eye (U. Heberlein, *et al.*, *Cell* 75: 913, 1993; and C. Ma, *et al.*, *Cell* 75: 927, 1993). In leg and wing discs, ectopic expression of *hh* has also been shown to yield pattern duplications and defects and is associated with induction of ectopic expression of other signaling molecules normally expressed in a zone along the anterior/posterior compartment boundary (T. Tabata and T. B. Kornberg, *Cell* 76: 89, 1994; and K. Basler and G. Struhl, *Nature* 368: 208, 1994).

For studies of signaling in imaginal discs, a thermal cycler was utilized to subject larvae carrying heat shock-inducible *hh* constructs to successive rounds of heat shock and recovery. The effects of temperature cycling upon expression of *dpp* and *wg* in imaginal discs was examined by monitoring  $\beta$ -galactosidase expression from a reporter gene carrying *dpp* promoter sequences or from an enhancer detector P element inserted in the *wg* gene. In FIGURE 7, X-gal staining was used to follow expression of *wg* FIGURE 7 (A-C) or *dpp* FIGURE 7 (D-L) in imaginal discs of late third-instar larvae that carry *wg-lacZ* or *dpp-lacZ* reporter genes. Leg (A-F), wing (G-I) and eye-antennal discs (J-L) from control larvae (A, D, G, J), larvae carrying the *hshh* transgene (B, E, H, K) and larvae carrying the *hshh* H329A transgene (C, F, I, L) are displayed. In all panels anterior is to the left. Arrows highlight the following features: an ectopic patch of *dpp* expression in the anterior compartment of wing discs in *hshh* H329A larvae (I); and an ectopic band of *dpp* expression in eye portion of the eye-antennal disc anterior to the morphogenetic furrow (marked by the other band of *dpp* expression more posteriorly) in *hshh* larvae (K). Expansion into the anterior compartment of *wg* expression in leg discs, and *dpp* expression in leg and wing discs in *hshh* larvae is similar to that described for the ectopic expression of *hh*. Morphological changes in the anterior compartment of leg (B and E) and wing discs (H) were also as described (K. Basler and G. Struhl, *supra*). In contrast, discs from *hshh* H329A and control larvae showed very little change in *wg* and *dpp* expression, even under prolonged heat shock conditions and morphological changes were never observed. (M-O) The eye phenotypes of adult control (M), *hshh* (N) and *hshh* H329A (O) flies that were shocked during larval development in a manner similar to that of the imaginal disc experiments above. Duplicated eye structures were observed in *hshh*

-56-

flies, but never in *hshh* H329A flies. The arrow in (N) points to a thin strip of cuticle between the two eye structures. Other deformities were also seen in *hshh* flies (for example, compare the thorax in N to M).

Virgin female flies from the homozygous lines *hshh* (D. T. Chang et al., *Development*, 5 1994, in press), *hshh* H329A, and *y<sup>1</sup> w<sup>1118</sup>* were crossed to males from the homozygous BS3.0 line (bearing a P element *dpp* reporter construct on the 2nd chromosome, referred to as *dpp-lacZ*) (R. K. Blackman, et al., *Development* 111: 657, 1991) or the line *y; Sco/CyO, enlacZ11::wg* (bearing a *wg* reporter P element enhancer trap on a second chromosome balancer, called *wg-lacZ*) (J. A. Kassis, et al., *Proc. Natl. Acad. Sci. U.S.A.* 10 89: 1919, 1992). Progeny were grown at 25°C in aerated 0.5-ml microcentrifuge tubes containing yeast paste until the late second instar or early third instar stage of larval development. The larvae were then cycled continuously at 37° C for 30 minutes followed by 25° C for 90 minutes in a Perkin-Elmer thermal cycler until they reached the late third instar stage. They were subsequently dissected and stained with X-gal as described (M. 15 Ashburner, *supra*) or allowed to grow to adulthood for phenotypic analysis.

As shown in FIGURE 7A, *wg* expression normally occurs in a ventral sector of the leg disc along the anterior/posterior compartment boundary while *dpp* is expressed in the dorsal portion of the disc along this boundary (FIGURE 7D). Although thermal cycling of larvae carrying the wild-type *hh* gene produced abnormal leg disc morphology and 20 extensive ectopic expression of both target genes, as previously reported for ectopic *hh* expression (FIGURE 7B and E), the H329A construct produced little if any detectable difference in these patterns of expression (FIGURE 7, C and F). Ectopic *hh* expression in the wing disc also leads to morphological changes and expanded expression of *dpp* (compare FIGURE 7, G and H), but the H329A construct produced only an occasional 25 small patch of anterior ectopic expression (FIGURE 7I).

Ubiquitous expression of wild-type *hh* also leads to ectopic expression of *dpp* in the eye-antennal disc (compare FIGURE 7, J and K). In the antennal portion of this disc the

expansion of *dpp* expression resembles that observed in leg discs. In the eye portion of the disc *dpp* expression is observed at its normal location in the furrow; however, ectopic expression also occurs in the form of a second dorso-ventral band at a location somewhat anterior to the furrow, thus giving the appearance of an eye disc with two morphogenetic furrows (FIGURE 7K). Indeed, in adults derived from temperature-cycled larvae that carry the wild-type *hh* construct, an apparently duplicated eye structure such as that in FIGURE 7N can be observed, with two eye structures separated by a thin strip of cuticle (arrow). The H329A mutant protein, in contrast, did not induce expansion of *dpp* expression in either portion of the eye-antennal disc (FIGURE 7L), and does not induce eye duplications or cuticle defects in the adult (FIGURE 7O).

The experiments described thus far comprise multiple series of larvae subjected to two days of thermal cycling followed by immediate dissection for analysis of imaginal structures or further incubation at constant temperature for analysis of adult structures. Although the H329A protein appeared to have little activity in these experiments, the small patch of ectopic *dpp* expression induced in the wing disc (FIGURE 7I, arrow) suggested that some residual activity remained. This suggestion was borne out in a similar experiment involving three days of cycling prior to dissection: the H329A protein clearly displayed some *dpp*-inducing activity in this experiment, presumably as a result of the higher amounts of protein that accumulated during the longer cycling period. The wing in particular, but also other imaginal discs, displayed low and variable amounts of ectopic *dpp* expression. This expression in all cases was far less extensive than that observed for the wild-type construct examined in parallel; furthermore, morphological deformations of the imaginal discs, although quite common with the wild-type protein, were extremely rare with the H329A protein. Although its potency is greatly reduced relative to wild-type, the H329A protein retained at least some activity in early embryonic and imaginal disc induction of *wg* and *dpp* expression; in contrast, even under heat shock conditions far more severe than those required for effects by the wild-type protein, the H329A mutant remained completely inert with respect to the re-specification of cell fates in the dorsal cuticle of the larva.

**EXAMPLE 6**  
**DIFFERENTIAL RELEASE OF N AND C**  
**INTO CULTURED CELL SUPERNATANTS**

5 A puzzling feature of *hh* function is its apparent short-range action in settings such as embryonic and imaginal disc signaling to *wg* and *dpp*, and longer-range action in other settings, such as patterning of the dorsal larval cuticle. These observations and the existence of two major protein products in vivo prompted us to look for differences in the solubility or diffusibility of N and C expressed in S2 cultured cells. FIGURES 8 (A) and (B) are immunoblots of cell pellets (lane 1) or supernatants (lane 2) from transfected S2  
10 cell cultures expressing *Hh* protein, developed with Ab1 (A) and Ab2 (B). Samples in each lane were from the same volume of resuspended total culture. Whereas N remained mostly associated with the cell pellet (compare lanes 1 and 2 in A), C was nearly quantitatively released into the supernatant (compare lanes 1 and 2 in B). U displayed partitioning properties in between those of N and C (A and B). (8C) demonstrates the  
15 heparin binding activity of various *Hh* protein species generated by *in vitro* translations with microsomes. Samples were: total translation mix (lane 1); supernatant after incubation with heparin agarose or agarose (control) beads (lanes 2 and 4); and material eluted from heparin agarose or agarose beads after washing (lanes 3 and 5). F, U, N<sub>ss</sub> and N fragments are depleted from reactions incubated with heparin agarose but not agarose  
20 beads (compare lanes 2 and 4 to 1), and the same species subsequently can be eluted from the heparin agarose but not the agarose beads (compare lanes 3 and 5 with lane 1). FIGURES 8, A and B indeed show that these proteins behave differently, with most of the N fragment remaining cell-associated and all, or nearly all, of C being released into the culture supernatant.

25 One possible explanation for this differential behavior might be association of the N fragment with extracellular matrix proteins on the surfaces of the S2 cells. Accordingly, the relative affinity of these two proteins for heparin agarose was examined, since heparin binding is a common property of proteins that associate with the extracellular matrix.

-59-

Given the obvious difficulty in obtaining soluble N from cultured cells, in vitro translation in the presence of microsomes was used to generate soluble, labelled N and C. As shown in FIGURE 8C, N but not C is depleted from these translation extracts by treatment with heparin agarose beads, while treatment with unmodified agarose beads did not deplete either fragment. Furthermore, N but not C was retained upon the heparin agarose beads upon extensive washing with a solution that contains 0.1% Triton X-100 and 150 mM NaCl; in contrast, neither fragment was retained by unmodified agarose. N, but not C, binds tightly to heparin, and this behavior suggests that the low concentration of N released into culture supernatants may be the result of binding to the extracellular matrix. Another mechanism that might contribute to the differential release of N and C into culture supernatant would be the expression in S2 cells of a receptor for N but not for C. Our current data can not distinguish these possibilities.

**EXAMPLE 7****DISTINCT EMBRYONIC LOCALIZATIONS OF N AND C**

The differential release of N and C into cultured cell supernatants suggested the possibility that these fragments might also be differentially localized in embryos. Previously reported *hh* protein localizations utilized either antibodies specific for N epitopes or antibodies unable to distinguish between N and C. FIGURE 9 shows the differential localizations of N and C in embryos by in situ localization of the *hh* transcript. FIGURE 9 (A) is shown in comparison to the distribution of N and C epitopes detected with Ab1 and Ab2 in panels (9B) and (9C), respectively. Note that the distribution of N and C epitopes span approximately one-third and one-half of each segmental unit respectively, while the transcript is limited to approximately one-quarter of each unit. In (9D), the localization of C epitopes in embryos homozygous for the *hh*<sup>13E</sup> allele is detected with the use of Ab2. C epitopes in this mutant, which displays impaired auto-proteolytic activity are more restricted, and resemble the wild-type localization of N. Homozygous *hh*<sup>13E</sup> embryos were identified by loss of a marked balancer from a heterozygous parent stock. All embryos are at mid to late stage 9 (extended germ-band).

FIGURE 9B shows in accordance with these reports, Ab1, which is specific for N epitopes, reveals a segmentally localized distribution that is slightly broader than that of the *hh* transcript at the same stage (FIGURE 9A). Also consistent with these reports, we observed that N epitopes at later stages accumulate in large punctate structures. Our analysis here concentrates on the earlier stage, when antibody staining is weaker but before formation of the invaginations and grooves that later crease the epidermis and thereby complicate the interpretation. Ab2 was also utilized to detect C-specific epitopes with a variety of fixation and staining procedures. Although detection of C epitopes above background is more difficult than for N, we consistently observed a segmentally modulated pattern, albeit with a broader distribution than N (FIGURE 9C). This localization is also distinctive in that C epitopes at early or late stages are not found in the punctate structures characteristic of N.

-61-

The *hh*<sup>13E</sup> mutation encodes a prematurely truncated protein that is missing 15 residues normally present at the COOH-terminus. Because this protein displays a much reduced efficiency in auto-proteolysis the distribution of C in this mutant background was examined. FIGURE 9D shows that C epitopes in a homozygous *hh*<sup>13E</sup> embryo (identified by absence of a marked balancer) are distributed in a much tighter segmental pattern than in wild-type. This localization resembles that of N, and we thus conclude that the broad distribution of C epitopes normally seen is altered in *hh*<sup>13E</sup> by retention of the uncleaved precursor near the site of synthesis.

### **EXAMPLE 8**

#### **THE ROLE OF AUTO-PROTEOLYSIS IN BIOGENESIS OF ACTIVE HEDGEHOG PROTEIN**

In addition to signal cleavage, the *hh* protein undergoes auto-proteolysis at an internal site to generate the predominant protein species observed *in vivo*. All or most of the amino acid residues required for this auto-proteolysis function map to C, the carboxy-terminal product of this internal cleavage. In an effort to determine the importance of auto-proteolysis for function, we introduced a single residue mutation (H329A) that blocks auto-proteolysis of the *hh* protein *in vitro* and demonstrated that both processing and function of this protein is impaired *in vivo*. Since similar levels of induced protein were detected from a strain carrying the wild-type construct or from several strains carrying independent insertions of the mutant construct (FIGURE 5), the impaired function of the H329A protein relative to wild-type is not the result of reduced levels of expression. Further evidence in support of a role for auto-proteolysis derives from the effect of the *hh*<sup>13E</sup> mutation, which reduces but does not eliminate auto-proteolysis of the *hh* protein *in vitro* (FIGURE 4). Correspondingly, the *hh*<sup>13E</sup> mutation is associated with a phenotype of intermediate strength *in vivo* (J. Mohler, *supra*).

Curiously, the H329A *Hh* protein appears to retain weak activity in embryonic signaling to induce ectopic *wg* expression and, to a lesser degree, can function in imaginal disc

-62-

signaling for induction of ectopic *wg* and *dpp* expression. In contrast to its retention of at least some signaling functions in embryonic and imaginal tissues, the H329 protein is completely inert when assayed for the ability to reprogram cell fates in the dorsal cuticle of the larva.

5       The assays in which the H329A protein is active or partially active involve short-range signaling that normally occurs across one or at most several cell diameters; in contrast, the H329A protein fails to exert any effect upon patterning of the dorsal cuticle, a long-range activity that normally operates across most of the segment. Previous proposals to account for long-range patterning activities have suggested that *hh*  
10       expression induces other signaling molecules which are then responsible for executing the patterning functions (the signal relay model; see FIGURE 10A). FIGURE 10 shows a signal relay versus dual function models for *hh* protein action. In FIGURE 10 (A), the long-range effects of *hh* signaling are achieved indirectly through short-range induction of a second signaling molecule (X). Based on its biochemical properties and its restricted  
15       tissue localization, N is presumed to represent the active short-range signal while the role of C would be limited to supplying the catalytic machinery required for biogenesis of N. In (10B), the long- and short-range signaling functions of *hh* are supplied by the N and C proteins derived by internal auto-proteolysis of the U precursor. N is implicated in short-range signaling by retention near its cellular site of synthesis, while C is less  
20       restricted in its distribution and would execute long-range signaling functions. In both models, auto-proteolysis is required to generate fully active signaling proteins. See text for further discussion.

These proposals seek to maintain a consistent mode of *hedgehog* action by rationalizing the apparent long-range activities of *hh* products as indirect consequences of short-range  
25       signaling. Based on the distribution observed, the active molecule in this model might be N and the role of C would then be limited to supplying the catalytic machinery required for biogenesis of N.

Our evidence suggests an alternative model, the dual function model (FIGURE 10B), in which long- and short-range activities of the *hh* protein might be executed by N and C, the two predominant forms of the molecule observed *in vivo*. The nearly quantitative release of C fragment into the culture medium of *hh*-expressing S2 cells and its broad, though segmentally modulated distribution within embryos suggests that C might execute or contribute to long-range signaling functions. The N fragment, on the other hand, predominantly remains associated with the expressing S2 cells and also binds to heparin, which suggests a possible association with the extracellular matrix. These properties and the segmentally restricted embryonic distribution of N are suggestive of a role in the execution of short-range *hh* signaling activities. Since the vertebrate *Hh* proteins we tested also appear to be auto-processed and also carry predicted heparin binding sites just carboxy-terminal to their signal sequences (H. Roelink et al., *supra*), many aspects of the dual function model discussed here in the context of *Drosophila* development may also apply to *hh* protein function in vertebrate development.

Execution of short-range functions by N would be consistent with the observation that the H329A mutant protein has at least partial function in signaling for the induction of *wg* and *dpp*, since this mutation does not alter residues located in the amino-terminal portion of the protein that normally would give rise to N. The uncleaved H329A protein thus would carry all the residues that normally interact with a presumed receptor for N, although there might be some effect on the affinity of the interaction due to the presence of carboxy-terminal sequences, thus accounting for the decreased potency of the H329A protein. Alternatively, the partial function of H329A protein may derive from an extremely small fraction of protein that appears to be cleaved, a very faint band with identical mobility to C appears in *in vitro* translations with the H329A protein (FIGURE 4, lane 3). Execution of long-range functions by C is also consistent with our observations because long-range signaling might require the release of the C fragment or otherwise require the H329 residue for some function other than for cleavage.

-64-

When N is synthesized from a native construct (wild type hh), it remains primarily cell-associated (FIGURE 10C), however, N generated from a truncated construct in cultured cells predominantly enters the culture medium (FIGURE 10D) (For constructs, see Porter, *et al.*, *Nature*, 374:363, 1995). These results further confirm that autoprocessing by  
5 fragment C may regulate the degree of N association with the cell surface and therefore its range of action.

### **EXAMPLE 9**

#### **ISOLATION OF HEDGEHOG HOMOLOGUES**

The mouse and human *hh*-like sequences were isolated by polymerase chain reaction  
10 (PCR) using primers degenerate for all possible coding combinations of the sequences underlined in FIGURE 1 of Chang, *et al.*, (*Development*, 120: 1994). PCR amplifications contained from 100 ng to 2 µg genomic DNA (depending upon the genome size of the species), 2 µM of each primer, 200 µM dNTPs (Pharmacia), 1X reaction buffer (Boehringer-Mannheim) and 2.5 units Taq polymerase (Boehringer-Mannheim) in 50 µl  
15 reactions. Amplification was as follows: 94°C 5 min, addition of Taq polymerase at 75°C, followed by 94°C 1 min, 52°C 1.5 min and 72°C 1 min for 30 cycles and a final extension of 72°C for 5 min. All PCR products were cloned into pBluescript (Stratagene) prior to sequence determination.

Mouse clones obtained in this manner contained 144 bases of sequence between the  
20 primer ends and were labelled with [ $\alpha$ -<sup>32</sup>P]dATP and used for high stringency screens of mouse cDNA libraries made from whole 8.5 dpc embryonic RNA and from 14.5 dpc embryonic brain in the λZAP vector (a gift from A. Lanahan). Several clones corresponding to *Hhg*-1 were isolated and the largest, 2629 bp in length (pDTC8.0), was chosen for sequence analysis using dideoxy chain termination (Sanger, *et al.*, 1977) and  
25 Sequenase v2.0 (US Biochemicals). Compressions were resolved by using 7-deaza-guanosine (US Biochemicals). Sequence analysis made use of the Geneworks 2.0 (IntelliGenetics) and MacVector 3.5 (IBI) software packages.

One of the three mouse clones, *Hhg-1*, when used as a probe, yielded a 2.0 kb clone from a 8.5 dpc mouse embryonic cDNA library and a 2.7 kb clone from a 14.5 dpc embryonic cDNA library. The 2.7 kb cDNA appears to represent a nearly full length mRNA because it corresponds to a 2.7 kb band detected by hybridization on a Northern blot. The largest methionine-initiated open reading frame within this cDNA encompasses 437 codons, and is preceded by one in frame upstream stop codon. Sequence comparisons indicate that the protein encoded by *Hhg-1* is identical to the independently characterized mouse *Shh* (Echelard, *et al.*, *Cell*, 75:1417-1430, 1993) except for an arginine to lysine difference at residue 122. *Hhg-1* also corresponds closely to the rat *vhh-1* gene (97% amino acid identity; Roelink, *et al.*, *Cell*, 76:761-775, 1994), the chicken Sonic hedgehog (81% identity; Riddle, *et al.*, *Cell*, 75:1401-1416, 1993) and *Shh* from the zebrafish (68% identity; Krauss, *et al.*, *Cell*, 75:1431-1444, 1993; Roelink, *et al.*, *Cell*, 76:761-775, 1994). The PCR-generated fragments *Hhg-2* and *Hhg-3* appear to correspond to the Indian and Desert classes of mouse hedgehog genes, respectively (Echelard, *et al.*, *Cell*, 75:1417-1430, 1993).

Alignment of the *Hhg-1* open reading frame with the two *Drosophila hh* sequences showed that all three proteins contain hydrophobic amino acid sequences near their amino-termini; the hydrophobic stretches within the *D. melanogaster* protein (residues 64 to 83) and within the mouse protein are known to act efficiently as signal sequences for cleavage (Lee, *et al.*, *Cell*, 71:33-50, 1992). Both *Drosophila* signal sequences are unusual in their internal locations, while the hydrophobic stretch of the mouse gene occurs at the extreme amino-terminus, a more conventional location for cleaved signal sequences. Although portions of sequence N-terminal to the *Drosophila* signal sequences are conserved, suggesting a functional role, the mouse gene lacks this region.

The overall level of amino acid identity between *Hhg-1* and *hh* carboxy-terminal to the signal sequences is 46%. A closer examination shows that the amino terminal portion, from residues 25 to 187, displays 69% identity, while remaining residues in the carboxy-terminal portion display a much lower 31% identity. Like *hh*, the *Hhg-1* coding sequence

-66-

is divided into three exons, and the boundaries of these exons are at the same positions within coding sequence as those of the three *Drosophila hh* exons. Curiously, the boundary between coding sequences of the second and third exons occurs near the transition from high to low levels of overall sequence conservation. The coincidence of these two boundaries suggests a possible demarcation of functional domains within these proteins. This location within *Hhg-1* coding sequence also coincides approximately with the site of a presumed proteolytic cleavage.

#### **EXAMPLE 10**

#### **HUMAN CLONING OF *hh* GENES**

Partial sequence for two human *hh* genes has been obtained by DNA sequencing of clones derived by PCR amplification from genomic DNA with *hh*-specific degenerate primers as outlined in Chang, *et al.*, (*Development*, 120:3339, 1994) and EXAMPLE 9 (FIGURE 11A and B). More extensive screening by the same approach, either with the same primers or with other primers from the *hh* coding region or with the human *hh* fragments seen in FIGURES 11A and B, is expected to yield at the least a third gene, and possibly more, since at least three genes are found in the mouse. These segments of human *hh* genes can be used to obtain full coding sequences for human proteins by the following cloning method commonly used by those of skill in the art and which are extensively described in the literature.

For example, ready-made cDNA libraries or RNAs from a variety of human sources, including various fetal stages and organs (from abortuses) and specific infant or adult organs (from pathological or autopsy specimens), are being tested for the presence of *hh* sequences by PCR or RT-PCR using the primers described in Chang, *et al.*, *supra*, and other primers derived directly from the sequence of the human fragments. Ready-made libraries containing *hh* sequences are being screened directly and, where necessary, new libraries are being constructed by standard methods from RNA sources containing *hh*

-67-

sequences. The probe for these screens is a mixture of all the distinct human *hh* fragments. Sequences of cDNA clones can then be determined. Most clones containing the probe sequences, which are located in the N region, will also include a full C coding region since standard methods of library construction result in cDNA clones that are most  
5 complete at their 3' ends. All full length *hh*-coding sequences obtained previously in vertebrates and invertebrates contain N and C sequences encoded in a single RNA. Screening is continued until complete open reading frames that correspond to all of the fragments of human *hh* genes are obtained. Specifically,  $1.2 \times 10^6$  clones from a human fetal brain library (Stratagene, La Jolla, CA) was screened using a mixture of the two  
10 human *hh* fragments (FIGURE 11A and B) as probes. Twenty-nine clones were identified as specifically hybridizing with these probes.

Second, the RNA sources identified as containing *hh* sequences can be used as templates from anchored PCR (also referred to in the literature as RACE, for rapid amplification of cDNA ends). Briefly, this method provides a means to isolate further mRNA sequence  
15 in either the 5' or 3' direction provided that sequence is known from an internal starting point. Anchored PCR can also be used to isolate sequences from cDNA library.

Third, genomic libraries can be screened with the probes described in the first technique. Where necessary, human *hh* exons and coding sequences are being identified by hybridization to previously isolated human and mouse coding sequences by sequence  
20 determination, and by exon-trapping methods to identify all *hh* coding sequences within genomic clones; these coding sequences can be "stitched" together by standard recombinant DNA methods to generate complete *hh* open reading frames.

FIGURE 12 A and B show *in vitro* cleavage reactions of a *Drosophila hh* protein produced in *E. coli* and purified to homogeneity. This protein has residues 89-254  
25 deleted, rendering it more soluble and easier to purify. It also contains a His<sub>6</sub> purification tag appended to the N-terminus. Autoproteolysis of this protein is triggered by the addition of reducing agents (DTT), and the resulting product corresponds to the C

-68-

fragment identified *in vivo*. FIGURE 12, Panel A shows a time course of cleavage after initiation by addition of DTT. Panel B shows incubations of concentrations ranging over three order of magnitude for a fixed time period (four hours), with no difference in the extent of conversion to the cleaved form. This concentration-independent rate of cleavage indicates an intramolecular mechanism of cleavage. Panel C shows the sequence around the cleavage site as determined by amino-terminal sequence of the cleaved fragment C. The cleavage site is denoted by the arrow, and the actual residues sequenced by Edman degradation of the C fragment are underlined. Panel C also shows an alignment of all published vertebrate *hh* sequences plus some of unpublished sequences from fish and *Xenopus*. The sequences shown correspond to the region of *Drosophila hh* where the cleavage occurs, and demonstrates the absolute conservation of the Gly-Cys-Phe sequence at the site of cleavage. Panel D shows a SDS-PAGE gel loaded with *in vitro* transcription/translation reactions as described in the previous Examples, using various *hh* genes as templates. *dhh* is *Drosophila*, *twhh* and *zfshh* are the *twiggy-winkle* and *sonic hh* genes of the zebrafish, and *mshh* is the *shh/Hgh-1/vhh-1* gene of the mouse. The translation mix included <sup>35</sup>S-labelled cysteine, used to visualize the resulting products by autoradiography. Note that each gene give a larger product (the precursor or U) and two smaller products of cleavage (N and C). The larger species is C for each of the vertebrate genes, whereas the *Drosophila* N is larger than C due to the presence of -60 residues occurring amino-terminal to the signal sequence that are present in the vertebrate open reading frame. This panel shows that vertebrate *hh* proteins are processed similarly to the *Drosophila* protein. Panel E shows that Edman degradation of the C fragments releases <sup>35</sup>S counts on the first but not subsequent rounds for all these proteins, indicating that the site of autoproteolytic cleavage for all of these *hh* proteins is the amide bond to the amino-terminal side of the Cys residue that forms the center of the conserved Gly-Cys-Phe sequence highlighted in panel C. This is a generalizable approach to establish the composition of protein fragments from any other *hh* family members.

**EXAMPLE 11**  
**DIFFERENTIAL EXPRESSION OF TWO *hh* GENES IN AXIAL**  
**MESODERM AND IN NEURAL PROGENITORS.**

Partial sequences corresponding to five distinct zebrafish *hh*-like genes were isolated and  
5 the complete coding sequences for two of these genes were obtained from an embryonic  
cDNA library. One of these two sequences is identical to that of the zebrafish *nhh-1* gene  
(Roelink, *et al.*, *Cell*, 76:761, 1994), and appears to correspond to the *shh* gene reported  
by Krauss, *et al.*, (*Cell*, 75:1431, 1993) (See FIGURE 13 description); the other gene,  
*tiggy-winkle* (Potter, B., The Tale of Mrs. Tiggy-Winkle, *The Penguin Group*, London,  
10 1905), represents a novel vertebrate *hh*. Coding sequences for both are shown in  
alignment to mouse and chicken sequences of the *sonic/vhh-1* class (FIGURE 13b). Like  
other vertebrate *hh* homologues, the *twhh* and *shh* proteins contain an amino-terminal  
stretch of hydrophobic residues. These residues function as signal sequences since  
cleavage is observed when coding sequences are translated in the presence of micro-  
15 somes; vertebrate *hh* genes thus appear to encode secreted proteins, as previously  
reported for *Drosophila hh* (Kimmel C.B. & Warga, R.M., *Developmental Biology*,  
124:269-280, 1987; Warge, R.M., & Kimmel, C.B., *Development*, 108:569-580, 1990).

The first four sequences were isolated from zebrafish genomic DNA (a gift from J.  
Pellegrino) using degenerate primers in polymerase chain reactions as described (Chang,  
20 *et al.*, *supra*). *twhh* and *shh* clones were isolated from a 20-28 hour cDNA library (a gift  
from R. Riggleman, K. Helde, D. Grunwald and J. Pellegrino) using the first three  
sequences as probes. The translational reading frames for *twhh* and *shh* were closed 12  
and 16 codons, respectively, upstream of the putative initiating methionine.

Figure 13 shows the predicted amino acid sequences are shown in single letter code.  
25 13(a) shows sequences common to five distinct *hh*-like genes are shown with a dot  
indicating identity with the corresponding residue of zebrafish *twiggy-winkle* (*twhh*;  
Potter 1905; *supra*), *hh*[zfb] and *hh*[zfc] is more diverged and appears to represent a

-70-

novel class. 13(b) shows amino acid sequences of *twhh* and *shh* are aligned to those of the *sonicvhh-1* class from chick and mouse (Riddle, *et al.*, *Cell*, 75:1401-1416, 1993; Chang, D.T., *et al.*, *Development, supra*; Echelard, Y., *et al.*, *Cell*, 75:1431-1444, 1993). Zebrafish *sonic hedgehog* (*shh*) is identical in sequence to *z-vhh-1* reported by Roelink, *et al.*, *Cell*, 76:761-775, 1994. Based on expression and extensive sequence identity throughout most of the coding region, *vhh-1* and the *sonic* sequence reported here probably correspond to *shh* of Krauss, *et al.*, *Cell*, 75:1431-1444, 1993, diverges dramatically throughout a 26 residue stretch near the carboxy-terminus. Rat *vhh-1/sonic hh* (Roelink, *et al.*, *supra*) was excluded in this alignment because of its 97% sequence identity to the predicted mouse protein. Residues identical in all four sequences are boxed, and a dash indicates a gap in the alignment. The arrow indicates the predicted signal sequence cleavage site (von Heijine, G., *Nucleic Acids Res.*, 14, 4683-4690, 1986) for *twhh*. The amino-terminal hydrophobic stretch common to all four *hh* genes is shaded. 13(c) shows percent identity of residues carboxy-terminal to the hydrophobic region.

Figure 14 shows a comparative expression of *twhh*, *shh*, and *pax-2* during zebrafish embryogenesis. Whole mount *in situ* hybridizations on 0-36 hour embryos were performed using a modification of the procedure of Tautz and Pfeifle, *Chromosoma*, 98:81-85, 1989, with antisense probes. Transcript localization is revealed by the purple product of an alkaline phosphatase enzymatic reaction. Staging of the embryos is according to Westerfield, M., (*The Zebrafish Book*, University of Oregon Press, Eugene, 1993). Transcripts were visualized by *in situ* hybridization to whole embryos. (a, b) *twhh* expression in a single late shield stage embryo. (a) Dorsal view, animal pole is to the top. The triangular shape of expression is characteristic of axial mesoderm-forming cells of the hypoblast (Statchel, S.E., *et al.*, *Development*, 117:1261-1274, 1993). (b) Lateral view: the thicker layer of cells on the left (dorsal) side of the embryo is the embryonic shield; the two arrows indicate the *twhh*-expressing hypoblast cells and the non-expressing epiblast. Anterior is to the left in all subsequent embryos. Dorsal is to the top in all lateral views. (c, d) A single embryo at the end of gastrulation (100% epiboly)

with *twhh*-expressing cells. (d) Caudal-dorsal view. Note the wide patch of stain in the presumptive tailbud which narrows anteriorly. (e, j) Early somitogenesis (11.5 hour, 3-4 somite) embryos; optic vesicles have not begun to evaginate from the wall of the diencephalon. (e, h, k) Lateral views of developing brain. (f, i, l) Dorsal views of developing brain. (e, f, g) Localization of *twhh*-expressing in a single row of cells that will form the floor plate. The arrowhead marks a patch of *twhh*-expressing cells lateral to the tailbud. (h, i, j) Localization of *shh*. *shh* is also expressed strongly in the protuberance. (j) Lateral view of the developing tail. *shh* is also expressed strongly in the protuberance. (j) Lateral view of developing tail. *shh* is expressed in cells that will form both floor plate and notochord. (k, l, m) Localization of *pax-2* during early optic vesicle formation; (m) also shows *twhh* expression. (k) 12 hour (4-5 somites) embryo. (l) 12.5 hour (5-6 somites) embryo. Expression of *pax-2* in the developing optic vesicle is in a gradient away from the protuberance. Note the expression of *pax-2* (asterisk) at the future midbrain-hindbrain border. (m) *twhh* (arrow) and *pax-2* expression in a 6-7 somite (13 hour) stage embryo. Note differential expression of *twhh* in ventral neural keel (corresponding to neural tube in other vertebrates). (n-s) Embryos at end of somitogenesis (22-24 hours). (n, o, p) Localization of *twhh*. (n, o) Developing brain. Note isolated groups of cells staining in the diencephalon (filled triangles) and the protuberance (arrowhead), and floor plate expression underlying the midbrain and hindbrain. The floor plate expression is contiguous caudally along the axis. (n) Lateral view. (o) Dorsal view. (p) Lateral view of tail. Expression is restricted to the floor plate. (q, r, s) Localization of *shh*. (q, r) Developing brain (q) Lateral view. *pax-2* expression in the optic vesicle is indicated. (r) Dorsal view. Expression in the protuberance (arrowhead) and in the neural keel. (s) Lateral view of tail. Expression is strongest in the floor plate, but contrary to the report of Krauss, *et al.*, supra, is still also in the notochord. Abbreviations: white e - epiblast; h - hypoblast; tb - tailbud; p - protuberance; c - eye; ov - optic vesicle; ot - otic vesicle; fp - floor plate; nc - notochord; asterisk - midbrain-hindbrain boundary or *pax-2*-labeled prospective midbrain-hindbrain boundary; t - telencephalon.

-72-

Comparison of *twhh* and *shh* expression patterns (Krauss, *et al. supra*), reveals that both gene are predominantly expressed in midline structures, albeit with notable differences in regard to timing, rostra-caudal extent, and tissue restriction. Expression of *twhh* is first detected during gastrulation in the dorsal mcsoderm (FIGURE 14a, b); this expression occurs in a band corresponding to a subset of the embryonic shield, a structure, analogous to Spemann's organizer in *Xenopus* (Stachel, *et al., Dev.*, 117:1261-1274, 1993, and reference therein; Ho., R., *Seminars in Developmental Biology*, pg.3, 1992). In concert with the movements of convergence and extension, this band of *twhh* expression shortens along the equatorial plane and extends along the incipient embryonic axis until, by the end of gastrulation, expression occurs throughout the entire axis (FIGURE 14c,d). Early in somitogenesis, *twhh* RNA is found restricted to presumptive ventral neural tissue along the entire body (FIGURE 14e, f, g), the only exception being cells in and near the tailbud (FIGURE 14g). In contrast to the neural restriction of *twhh*, *shh* is localized both to presumptive neural and notochordal cells (FIGURE 14j).

As somitogenesis proceeds, ventral midline expression of *shh* and *twhh* is reduced in most of the prospective forebrain, but remains strong in an anterior patch of midline cells within the floor of the prospective diencephalon (FIGURES 14e, f, for *twhh*; FIGURES h, i for *shh*). This patch later will give rise to the protuberance (Schmitt, E.A. and Dowling, J.D., *J. Comp. Neur.*, 344:532-542, 1994), an anterior extension of the diencephalon. This structure, which is medial and just rostral to the developing optic stalks, is the site we propose as the focus of early patterning activity for the developing eyes (see below). By the end of somitogenesis, both *twhh* and *shh* are strongly expressed in the floor plate (FIGURES 14p, s), although *shh* transcripts remain detectable in the notochord at this stage and at 36 hours of development (FIGURES 14s; later stage not shown). At 28 hours, *twhh* transcripts are also found in a small cluster of cells within the first gill arch (not shown), as also reported for *shh* at 33 hours of development (Krauss, *et al., supra*).

-73-

Differences between *twhh* and *shh* expression are apparent from the beginning of gastrulation, since *twhh* RNA can be detected as early as the shield stage while *shh* is first detected later, at about 60% epiboly (not shown; (Krauss, *et al.*, *supra*). In addition, *twhh* transcripts are restricted to neural tissues early in development, and are never detected in the notochord (compare FIGURE 14g to FIGURE 14j). Later differences in expression include differential rostra-caudal restriction within the diencephalon and midbrain and weaker and more restricted expression of *twhh* in the protuberance (compare FIGURES 14n and 14q), such that the later domain of *twhh* expression in the brain appears to constitute a subset of the *shh* domain. In addition, *shh* but not *twhh* is expressed in the developing fin bud (Krauss, *et al.*, *supra*). Comparison of *shh* and *twhh* expression patterns to this previously reported for *hh* homologues in zebrafish and other vertebrate species indicates that *shh* is the zebrafish homologue of the *sonic/vhh-I* class while *twhh* represents a novel class of vertebrate *hh*.

#### **EXAMPLE 12**

##### **DEVELOPMENTAL CONSEQUENCES OF ECTOPIC *hh* EXPRESSION DURING ZEBRAFISH EMBRYOGENESIS**

To gain insight into the potential roles of *hh* products in development, synthetic *twhh* and *shh* mRNA was injected into 1-8 cell embryos. This technique yields a mosaic but fairly uniform pattern of expression, as determined for the control mRNA encoding  $\beta$ -galactosidase (not shown). Uniformity of expression is in good agreement with fate mapping studies of the early zebrafish embryo (Kimmel & Warga, *supra*; Warga & Kimmel, *supra*; Heide, *et al.*, *Science*, 265:517-520, 1994), which indicate that blastomeres undergo extensive cell mixing during the cleavages prior to gastrulation. We note that mosaicism of expression caused surprisingly little variation in the phenotypes of the *hh* injected embryos, possibly due to secretion of *hh* gene products.

Embryos injected with synthetic *twhh* or *shh* mRNA (*hh* RNA) exhibited numerous yet highly reproducible abnormalities in comparison to control embryos injected with *lacZ*

-74-

mRNA. These abnormalities, discussed below, are primarily defects in the brain and eyes. Although the effects of ectopic *twhh* and *shh* expression were qualitatively similar, the incidence and severity were greater with *twhh* RNA (see text below, FIGURE 15 and FIGURE 16). The proteins encoded by these two genes have qualitatively similar biological activities, but apparent differences in potency.

FIGURE 15 shows the effects of ectopic *hh* on zebrafish development. Wild type zebrafish, *Danio rerio*, (Eckwill Waterlife Resources) were maintained at 28.5°C, some embryos were then cultured overnight at RT. Zebrafish embryos were injected at the 1-8 cell stage with *twhh*, *shh*, or *lacZ*RNA and examined at 28 h of development. (a-c) Dorsal view of the midbrain-hindbrain region; anterior is left. (a) *lacZ*. (b) *twhh*. (c) *shh*. (d-f) Frontal optical section of the forebrain region; anterior is up. (d) *lacZ*. (e) *twhh*. (f) *shh*. (g-i) Lateral view of the eye region; anterior is left. (g) *lacZ*. (h) *twhh*. (i) *twhh*. At levels caudal to the prospective brain, the notochord, somites, and neural keel formed by most *hh*-injected embryos appeared grossly normal except for an overall shortening and dorsal curvature of the axis. A minority of *hh*-injected embryos (15% are not shown) displayed partially bifurcated axes, containing duplicated axial mesoderm and parallel neural keels, each neural keel comprising ventral midline cells and some bilaterally symmetric lateral cells (not shown). Although we have not determined the primary cause of these axial defects, analysis of late gastrulation stage embryos suggests that the bifurcation may result from difficulties in epiboly and convergence. Abbreviations: mv - mesencephalic ventricle; rv - rhombencephalic ventricle; asterisk - midbrain-hindbrain boundary; ot - otic vesicle; tv - third (diencephalic) ventricle; r - retina or retina-like structure; l - lens or lens-like structure; pe - pigmented retinal epithelium.

Morphological defects in the brain and other rostral neural derivatives occur at high frequency in *hh*-injected embryos. The three ventricles of the fish brain normally apparent at 28 hours of development - the rhombencephalic, mesencephalic (FIGURE 15a), and diencephalic (third ventricle; FIGURE 15d) - are not formed in the brains of *hh* injectees (FIGURES 15b, c; FIGURES 15e, f), despite the obvious presence of a lumen.

The prominent constriction normally present at the midbrain-hindbrain boundary also is absent (compare FIGURE 15a to FIGURES 15b, c). Formation of this constriction requires function of *pax-2* (Krauss, *et al.*, *Nature*, 353:267-270, 1991; Krauss, *et al.*, *Nature*, 360:87-89, 1992), which normally is expressed in a band at the midbrain-hindbrain boundary (Krauss, *et al.*, *supra*; Krauss, *et al.*, *Development*, 113:1193-1206, 1991) *pax2* expression at this boundary is not disrupted by *hh* RNA injection, however, indicating that this phenotype does not result from disruption of rostra-caudal information.

Defects in eye development also occur at high frequency in embryos injected with *hh* RNA. Thus, while at 28 hours the normal zebrafish eye has a lens and a retina with pigmented epithelium (FIGURE 15d, g), *hh*-injected embryos usually fail to develop lenses and retinal pigmentation (FIGURE 15e, h). Eye duplications are also observed at low frequencies (FIGURE 15i). The poorly developed eyes do not appear to result from a simple delay in development since pigmentation elsewhere in injected embryos appears in its normal time course. Examined at three days of development, the consequences of *hh* RNA injection include defects that range from complete absence of eyes to partially formed eyes lacking a ventral portion of the retina.

The eye phenotypes caused by *hh* RNA injection resemble those produced by treatment of zebrafish and *Xenopus laevis* embryos with retinoic acid. In *Xenopus*, phenotypes range from reduction of the eye and absence of the lens to eyes with retinal folds (resembling duplicated eyes) and multiple small lenses (Manns, M. & Fritsch, B., *Neurosci. Lett.*, 127:150-154, 1991). In zebrafish, exposure to retinoic acid during gastrulation interferes with the formation of the eye (Holder, N. & Hill, J., *Development*, 113:1159-1170, 1991), while exposure during formation of the optic primordia induces formation of duplicated retinas and extra lenses (Hyatt, *et al.*, *Proc. Natl. Acad. Sci. USA*, 89:8293-8297, 1992). Patterning effects of retinoic acid upon the developing chick limb appear to be mediated through ectopic activation of the endogenous *sonic hh* gene (Riddle, *et al.*, *supra*), these results with ectopic *hh* expression suggest the possibility of

-76-

a similar mechanism underlying the patterning effects of retinoid acid treatment in the vertebrate eye.

### **EXAMPLE 13**

#### **hh EXPRESSION IN THE OPTIC VESICLE SPECIFIES PROXIMAL FATES AT THE EXPENSE OF DISTAL FATES**

5

To further elucidate the role of *hh* in eye development we utilized *pax-2* and *pax-6* (Krauss, *et al.*, *EMBO J.*, 10:3609-3619, 1991; Pitischel, *et al.*, *Development*, 114:643-651, 1992) were utilized as positional markers to examine the effects of ectopic *hh* expression on the optic vesicle. As the optic vesicle evaginates from the lateral walls of the zebrafish forebrain (Schmitt, E.A. & Dowling, J.D., *J. Comp. Neur.*, 344:532-542, 1994), *pax-2* is expressed in a gradient, with highest RNA levels in the anterior and ventral regions of the optic vesicle (Krauss, *et al.*, *supra*; FIGURE 14k, l, m). Immediately adjacent to the maximum of this *pax-2* expression gradient is the region of the diencephalon termed the protuberance (Schmitt & Dowling, *supra*), where both *twhh* and *shh* but not *pax-2* are strongly expressed (FIGURES 14e, f, h, i, m). The concentration gradient of *pax-2* expression in the optic vesicle thus appears to incline downward from its maximum at a location adjacent to the site of *twhh* and *shh* expression in the protuberance. Superposition of developmental fate within the optic vesicle (Schmitt, *et al.*, *supra*), upon the pattern of *pax-2* expression suggests that the gradient of *pax-2* RNA prefigures the future proximal/distal axis of the eye.

10

15

20

Ectopic *hh* alters the expression of *pax-2*, *pax-6*, and *F-spondin*. Zebrafish embryos were injected at the 1-8 cell stage with *twhh* or *shh* RNA and the pattern of *pax-2*, *pax-6*, or *F-spondin* expression was examined by whole mount *in situ* hybridization. Control embryos injected with *lacZ* RNA were performed in every case and displayed wild-type expression patterns. At embryo stage, the anterior-posterior axis of the optic vesicle corresponds to the future proximal-distal axis of the eye. During the next hour of

25

-77-

development, the posterior edge of the optic vesicle will separate from the diencephalon (Schmitt and Dowling, *Comp. Neur.*, 344:532-542, 1994).

Injection of either *hh* RNA causes uniform initiation of *pax-2* expression along both the proximal-distal and dorsal-ventral axes of the optic vesicle as it begins to evaginate. The  
5 ectopic *pax-2* expression appears at the same time as normal *pax-2* expression is initiated in the eye, and in some cases, is also seen in the diencephalon between the optic vesicles. At the end of somitogenesis, a time when *pax-2* would normally be restricted to the optic stalk, *pax-2* RNA in *hh* injected embryos is detected in all but the most distal portion of the optic vesicle.

10 The effects of ectopic *hh* on expression of *pax-6*, which encodes a transcription factor critical for eye development was also studied. At 22 hours of zebrafish development, *pax-6* is normally expressed in the lens and in most of the distal part of the optic cup (Krauss, *et al.*, *supra*; Puschel, *et al.*, *Development*, 114:643-651, 1992). In *hh*-injected embryos, *pax-6* is repressed in the optic vesicle, although many embryos retain *pax-6*  
15 expression in the most distal cells. With regard to *pax-2* and *pax-6* as markers of positional identity, *hh* expression in the optic vesicle can be characterized as inducing proximal fates and repressing distal fates.

The distal part of the optic vesicle is the most refractory to *hh*-induced changes in both *pax-2* and *pax-6* gene expression. Due to a later rotation, this distal portion of the optic  
20 vesicle will give rise to the dorsal portion of the mature eye (Schmitt, *et al.*, *supra*); interestingly, this is the portion of the eye that remains in 3-day old injected embryos with intermediate phenotypes (see above).

Lesions in the *pax-6* gene have been assigned as the basis for the *Aniridia* (Ton, *et al.*, *Cell*, 67:1059-1074, 1991; Glaser, *et al.*, *Nat. Genetics*, 2:232-239, 1992), *Small eye* (Hill,  
25 *et al.*, *Nature*, 354:522-525, 1992), and *eyeless* mutations (Quiring, *et al.*, *Science* 265:785-789, 1994), in humans, mice and *Drosophila*, respectively; *pax-6* function thus

-78-

appears to be critically required for eye development in *Drosophila* and mammals. As we argue here, *hh*-encoded activities also appear to play a role in vertebrate eye development, and this suggests a further molecular parallel between vertebrates and insects, since the role of *hh* in *Drosophila* eye development is well established (Mohler, *et al., supra*; Ma, *et al., supra*; Heberlein, *et al., supra*; Lee, *et al., supra*). The reciprocal and non-overlapping patterns of *hh* and *pax-6* expression in the developing *Drosophila* eye (Ma, *et al., supra*; Quiring, *et al., Science*, 265:785-789, 1994), suggest the possibility of *pax-6* repression by *hh*, but whether *hh* functions by similar mechanisms in vertebrate and *Drosophila* eye development is a questions that requires further investigation.

In mice, the dosage of *pax-6* protein is crucial for normal eye development (Hill, *et al., supra*). *Small eye* heterozygotes develop an abnormally small lens (Hogan, *et al., J. Embryol. Exp. Morph.*, 97:95-110, 1986; Hogan, *et al., Development*, 103 Suppl., 115-119, 1988), as do *hh*-injected embryos with weaker phenotypes (FIGURE 14f). *Small eye* homozygotes lacking lenses eventually generate and the animals lack eyes at birth (Hogan, *et al., supra*; Hogan, *et al., supra*), as do many of the *hh*-injected embryos at three days of development. These parallels suggest that many of the later eye defects observed in *hh*-injected zebrafish may be caused by partial or complete repression of *pax-6* during eye development.

20

#### **EXAMPLE 14**

#### **GENETIC ABLATION OF *hh* FOREBRAIN EXPRESSION CAUSES LOSS OF PROXIMAL FATES IN THE OPTIC VESICLE**

25

The patterns of *twhh* and *shh* expression (FIGURE 14) and the effects of ectopic *hh* expression (FIGURE 15) are consistent with a normal role for *shh* and *twhh* in eye development. If *hh* activities indeed play a normal role in promoting proximal fates within the developing eye, removal of *hh* activities would be expected to result in a loss of proximal fates. In embryos homozygous for the *cyclops* mutation ventral neural

structures fail to form and the developing eyes fuse at the midline,, yielding an embryo with a single eye (Hatta, *et al.*, *Nature*, 350:339-341, 1991). The missing ventral structures in *cyclops* mutants include the regions where we observe expression of *twhh* and *shh*, and we therefore examined the effects of the *cyclops* mutation on *hh* expression.

5 *cyc*<sup>b16</sup> (Hatta, *et al.*, *Nature*, 350:339-341, 1991), heterozygous adults (a kind gift of R. Riggelman) were spawned and their offspring analyzed by whole mount *in situ* hybridization. Detection of *pax-2* and either *twhh* or *shh* RNAs in embryos homozygous for the *cyc* mutation or their wild-type siblings. *twhh* RNA is only expressed in the presumptive tailbud (caret) of *cyc* embryos. As reported by Krauss, *et al.*, *Cell*, *supra*,  
10 neural expression of *shh* is abolished in *cyc* embryos. Strong *pax-2* expression was observed in the optic vesicles of wild-type embryos which is significantly reduced in *cyc* mutant embryos.

*twhh* RNA in *cyclops* embryos is found only in a small patch of cells at the presumptive tailbud and neural expression was not detected at any later stage examined. Neural  
15 expression of *shh* is also lost in *eye* mutants, although expression in the notochord is reunited (Krauss, *et al.*, *supra*; data not shown).

Since the *eye* mutation appears to ablate *hh*-expressing cells in the developing brain, this mutation can be used as a genetic tool to examine the requirement for *hh* function in eye development. Liatta, *et al.*; Hatta, *et al.*, *Proc. Natl. Acad. Sci. USA*, 91:2061-2065,  
20 1994), recently demonstrated that *pax-6* expression is fused at the midline due to loss of ventral midline cells that normally do not express *pax-6* and, in addition, *pax-2* expression in the fused eye of *eye* mutant embryos is reduced. We extended these observations to an earlier stage when the optic vesicles first form and found that *pax-2* expression is weak and fails to extend within the vesicles in *eye* mutants. In conjunction  
25 with the results of ectopic *hh* expression, these observations suggest that *hh* signaling that activity promotes and is required for the induction of proxima fates within the eye vesicle.

-80-

In this model, we propose that the protuberance acts as a proximal patterning center for the developing zebrafish eye by providing a localized source of *hh* activity.

### **EXAMPLE 15**

#### **hh ACTIVITY VENTRALIZES THE DEVELOPING BRAIN**

5 Previous work has established an important role of signals from the floor plate and notochord in ventral patterning of the neural tube (Jessell, T.M., & Dodd, J., *Cell*, 69:95-110, 1992). For example, Goulding, *et al.*, *Development*, 117:1001-1016, 1993, recently demonstrated that notochord and floor plate grafts can repress the normal lateral expression of *pax-6* in the neural tube. Other recent work has implicated *hh* activity in  
10 at least some aspects of ventral neural tube patterning (Echelard, *et al.*, *Cell*, 75:1417-1430, 1993; Krauss, *et al.*, *supra*; Roelink, *et al.*, *supra*); consequently, we examined *hh*-injected embryos for effects on *pax-6* expression in the brain.

In the zebrafish at 22 hours of development, *pax-6* is expressed in dorso-lateral regions of the diencephalon and in a ventro-lateral domain of the hindbrain and spinal cord that  
15 excludes the floor plate and adjacent cells (Krauss, *et al.*, *supra*; Puschel, *et al.*, *supra*). This pattern of expression is reciprocal to that of both *twhh* and *shh* in the diencephalon (compare FIGURES 14q and 14i) and in the hindbrain. *hh* RNA injection caused repression of *pax-6* in the more ventral domain in the diencephalon, while more dorsal expression persisted. In addition, *pax-6* expression was significantly reduced ventrally  
20 in rhombomeres 1, 2, and 4 and, in some cases, was completely abolished in these rhombomeres. The repressing effect of ectopically expressed *hh* and *pax-6* in normal embryos are due to repression of *pax-6* by nearby *hh* expressing cells.

Since absence of *pax-6* expression is a feature of the ventral midline, repression of *pax-6* in lateral positions suggests ventralization. Consequently, *twhh* was injected into  
25 embryos for analysis of induction of a floor plate marker, *F-spondin* (Riddle, *et al.*, *supra*). As described above, ectopic *twhh* induces *F-spondin* expression at more dorsal

-81-

levels in the midbrain and anterior hindbrain. The effects of *hh* upon expression of both *pax-6* and *F-spondin* indicate a ventralization of the brain. Adoption of ventral cell identity by lateral cells might explain their failure to form ventricles (FIGURE 15a-f).

5 The ventralizing activities of *twhh* confirm and extend those previously reported for *shh/vhh-1* class genes of chicken, zebrafish, and rat (Echelard, *et al.*, *supra*; Krauss, *et al.*, *supra*; Roelink *et al.*, *supra*). The early restriction of *twhh* to midline neural progenitors, however, suggests that it may play a specific role in the homeogenic mechanisms of floor plate maintenance and expansion (Placzek, *et al.*, *Dev.*, 117:205-218, 1993). In the zebrafish, wild type cells in *cyclops* hosts can contribute to and induce  
10 adjacent cells to form floor plate, but only when the transplanted cells populate the neural plate and not the notochord (Hatta, *et al.*, *Nature*, 350:339-341, 1991). We have demonstrated that, in *cyclops* mutants, midline expression of *twhh* is lost while *shh* expression is maintained in the notochord (FIGURE 18; Krauss, *et al.*, *supra* for *shh*); taken together, these results suggest that the homogenetic floor plate signal lost in the  
15 *cyclops* mutant may be encoded by the *twhh* gene. In the chick and rat, the floor plate retains auto-inductive potential long after the loss of floor plate inducing properties by the notochord, despite continued expression of *shh/vhh1* in the notochord (Roelink, *et al.*, *supra*; Placzek, *et al.*, *supra*; Yamada, *et al.*, *Cell*, 73:673-686, 1993). Although no homologues of the *twhh* class have been reported in other vertebrates, expression of other  
20 *hh* homologues in patterns more like those of *twhh* might help explain these discrepancies.

#### **EXAMPLE 16**

#### **TWO DISTINCT SIGNALING PROTEINS DERIVE FROM THE *twhh*-ENCODED PRECURSOR**

25 Endogenous *hh* protein in *Drosophila* is found predominantly as an amino- and a carboxy-terminal fragment (N and C, respectively) derived by an internal auto-proteolytic

-82-

cleavage of a larger precursor (U for uncleaved), which also occurs *in vivo* but at lower levels (Lee, *et al.*, *supra*). Determinants within the amino-terminal domain appear not to be required for auto-proteolytic activity, whereas mutations affecting the carboxy-terminal domain can block auto-proteolysis and reduce activity *in vivo* (Lee, *et al.*,  
 5 *supra*). The auto-proteolysis is blocked by a substitution of alanine for the histidine normally present at position 329. This histidine is absolutely invariant in alignments of all known *hh* genes, and its sequence context suggests a catalytic role in auto-proteolysis (Lee, *et al.*, *supra*).

FIGURE 17 shows zebrafish *twiggy-winkle hedgehog* derivatives. 17(a) Cartoons of various *twhh* open reading frames. SS (shaded) is the predicted N-terminal signal sequence for secretion of these proteins and encompasses the first 27 amino acids of each open reading frame. The arrow indicates the predicted internal site of auto-proteolytic cleavage. Amino acid residue numbers are according to Figure 13b. The filled triangle denotes the normal termination codon for the *twhh* open reading frame. Construct U<sub>HA</sub>  
 10 contains a mutation that blocks auto-proteolysis (the histidine at residue 273 is changed to an alanine; see Lee, J.J., *et al.*, *supra*). Construct U356<sub>HA</sub> contains a stop codon in place of amino acid residue 357 as well as the H273A mutation in U<sub>HA</sub>. Construct N encodes just the first 200 amino acids of *twhh*. Construct C has had the codons for residues 31-197 deleted. 17(b) shows *in vitro* translation of the expression constructs shown schematically in part a. Constructs were translated *in vitro* in the presence of <sup>35</sup>S  
 20 methionine and analyzed by autoradiography after SDS-PAGE. The protein products are shown schematically to the left. Lanes 1 and 6: Auto-proteolysis of the full-length (U<sub>SS</sub>) protein creates two fragments, an N-terminal fragment (N<sub>SS</sub>) and a C-terminal fragment (C). Lane 2: Construct U<sub>HA</sub> only makes an uncleaved form of *twhh* protein that comigrates with U<sub>SS</sub> *twhh* via auto-cleavage. Lane 5: Construct C encodes processed and unprocessed forms which are visible as two bands migrating closely together. The bottom band is the C protein made from auto-proteolysis of the U<sub>SS</sub> (Δ31-197). All constructs were made by *in vitro* mutagenesis of expression construct T7TStw<sub>hh</sub> (see  
 25 FIGURE 15) using the method of RPCR. The sequence of all constructs were confirmed

by dideoxy sequencing. *In vitro* translations were performed according to manufacturer's instructions (Promega).

The vertebrate *hh* proteins encoded by *shh*, *twhh* and mouse-*shh/Hhg-1* also undergo auto-proteolysis to yield two smaller species from a single larger precursor (Lee, *et al.*, *supra*; Chang, *et al.*, *supra*; see lanes 1 and 6 in FIGURE 17b). The invariant histidine to alanine mutation to generate a construct encoding a form of the *twhh* protein that is not auto-proteolytically cleaved (U<sub>HA</sub>). We have also introduced a nonsense codon and deleted a segment of coding sequence to generate constructs that produce either the amino- or the carboxy-terminal domains of *twhh* (N and C, respectively; see lanes 4 and 5 in FIGURE 17b); constructs are schematically diagrammed in FIGURE 17a). To target these proteins to the secretory pathway, all constructs retained the normal *twhh* signal sequence.

Synthetic mRNAs transcribed from these constructs were injected to examine the role of processing and to assay the activities of individual protein fragments; the results are summarized in Table I and are based on the activities presented in FIGURE 15. The most striking conclusion from these experiments is that N and C both exhibit activity, and that these activities are distinguishable. Thus, although both N and C are capable of ectopically activating *pax-2* in the developing eye, thereby providing an internal injection control, only N was capable of efficiently repressing *pax-6* (FIGURE 16). Later effects on lens development were also more extreme for N, consistent with the role of *pax-6* in lens development suggested by its mutant phenotypes in mice. (See Ton, C.C., *et al.*, *Cell* 67:1059-1074, 1991; Glaser, T., *et al.*, *Nat. Genetics* 2:232-239, 1992; Hill, R.E., *et al.*, *Nature* 354:522-525, 1991; Hogan, B.L., *et al.*, *J. Embryol. Exp. Morph.*, 97:95-110, 1986; and Hogan, B.L., *et al.*, *Development*, 103Suppl.:115-119, 1988.)

In considering the activity of delta N-C, it is important to recognize the activity of endogenous *hh* genes in these experiments, which are inhibited by delta N-C and fragments thereof. (see Example 18 and FIGURE 18 for further discussion)

-84-

The uncleaved U<sub>HA</sub> protein is only somewhat less active than C in inducing *pax-2*, but it also was not able to repress *pax6* efficiently (FIGURE 16). The latter is particularly notable since the U<sub>HA</sub> protein (U356<sub>HA</sub> ; see FIGURE 17a, b) has activities not significantly different from N (FIGURE 16). Thus, in addition to carrying determinants  
5 important for auto-proteolysis and *pax-2* induction, the C-terminus also contains a domain inhibitory to N-terminal function when in the context of the uncleaved *hh* protein. The C-terminus can also inhibit N action by an intermolecular mechanism (Lai, *et al.*, *supra*). The existence of such an inhibitory domain in C suggests that if autoproteolysis can be modulated, such modulation might regulate the activity of *hh in vivo*. This possibility  
10 highlights the importance of ascertaining the processed state of *hh* proteins expressed in any particular patterning center to understand the potential *hh* activities generated.

**EXAMPLE 17**  
**DUAL ROLES OF *hh* SIGNALING PROTEINS IN EARLY EYE**  
**AND BRAIN PATTERNING**

5 In understanding the normal roles of N and C in eye and brain patterning, the N and C derivatives of the *Drosophila hh* gene may offer some insight. The *Drosophila* N derivative is retained close to its embryonic site of synthesis in a segmentally striped pattern (Tabata and Kornberg, *Cell*, 76:89-102, 1994; Taylor, *et al.*, *Mech. Dev.*, 42 89-96, 1993), is cell-associated when expressed in cultured cells, and is effectively bound by heparin agarose *in vitro*, suggesting the possibility of extracellular matrix association.

10 The C-terminal fragment, in contrast, is not bound effectively by heparin agarose, is almost quantitatively released into the culture supernatant of expressing cultured cells, and is only diffusely localized in embryos. Although the activities of individual fragments have not been assayed, the biochemical differences and tissue distributions of *Drosophila* N and C may account for the short and long range nature of the functions

15 associated with *hh* during *Drosophila* development.

Although the tissue distributions of zebrafish N and C are not known, their activities in ectopic expression assays are also suggestive of short- and long-range functions when considered in the context of normal expression patterns of *hh*, *pax-2* and *pax-6*. The normal gradient of *pax-2* expression in the optic vesicle extends a substantial distance

20 from its maximum adjacent to the site of *hh* expression in the protuberance; the ability of ectopic C to activate *pax-2* therefore suggests that, consistent with the distribution of C in *Drosophila*, zebrafish C may carry out a long-range function. Repression of endogenous *pax-6* expression, in contrast, appears to be a short-range function since *pax-6* expression occurs close to endogenous *hh* expression. Efficient repression of *pax-6* is

25 an attribute of constructs producing N, and a short-range function for N would be consistent with the distribution of N in *Drosophila*.

-86-

Two types of *hh*-dependent activity have been reported for *hh*-transfected cultured cells. One is the apparent contact-dependent induction of floor plate markers (Roelink, H., *et al.*, *Cell* 76:761-775, 1994); the second induction of sclerotome markers in presomitic mesoderm, is diffusible and acts at long-range.

5

**EXAMPLE 18****CHARACTERIZATION OF XENOPUS *hh*****1. Materials and Methods**

cDNAs encoding full-length Xenopus hedgehogs, or encoding amino terminal or carboxy terminal domains linked to secretory leader sequences were transcribed *in vitro* to yield translatable messenger RNA. The synthetic messenger RNAs, and control mRNAs, were microinjected into the animal poles of cleavage stage Xenopus embryos, which were allowed to develop to the blastula stage, at which time the animal cap explants were prepared from the upper one fourth of the embryo. These blastula cap explants were then cultured *in vitro* in physiological saline in the presence or absence of the transforming growth factor beta family member, recombinant human activin A. All explants were allowed to develop until control embryos had grown to neurula stage, or to tadpole stage. Importantly, blastula caps left untreated differentiate from ectoderm into atypical epidermis. Blastula caps treated with activin differentiate into mesodermal and neural cell types. Thus, the question was whether hedgehog, or its proteolytic derivatives, would change the differentiation of cells away from becoming epidermis, and into another cell type. A second question was whether hedgehog can work with activin to alter the normal response of the tissue to either factor by itself.

Explants were then extracted to yield mRNA by methods commonly used by those of skill in the art, which was used as template with reverse transcriptase to yield cDNA. The cDNA was then used as template with various sets of primers for PCR for specific genes, reverse-transcriptase-polymerase chain reaction, or RT-PCR. This results in specific

-87-

amplification of radioactive products which are diagnostic for the presence and level of the messenger RNAs which were present in the explants. Samples were separated on polyacrylamide gels, which were exposed to X-ray film to yield the bands shown in the figures. Thus, the darker bands correspond to a greater level of the specific mRNA.

5      FIGURE 18A and B demonstrate that hedgehog induces pituitary and anterior brain genes, and can cooperate with activin or with neural inducers such as noggin and follistatin which are induced by activin to elevate expression of these genes in explanted embryonic tissue. All odd numbered lanes lack reverse transcriptase in the RT-PCR  
10      give specific bands to mRNA. In Panel A, Lanes 1-2 are control blastula caps, lanes 3-4 are *Xenopus* hedgehog-expressing blastula caps, lanes 5-6 are control blastula caps treated with activin, lanes 7-8 are hedgehog-expressing blastula caps treated with activin, and 9-10 are prolactin-expressing blastula caps treated with activin to serve as a control for simply expressing a secreted protein in the blastula cap. The primers used for the  
15      assay are shown to the left of each panel, *i.e.*, XAG 1 is a cement gland marker, XANF1B is a pituitary marker, otx-A is an anterior brain marker, en-2 is a midbrain-hindbrain boundary marker, krox 20 is a rhombomere-specific hindbrain marker, HHHbox 6 is a posterior hindbrain marker, NCAM is a general neural marker, activin is a control for mesoderm induction, and elongation factor is a positive control to shown that all even  
20      numbered lanes did in fact have cDNA present.

The panel labelled XANF1B detects a pituitary gene. Lane 4 (panel A) shows that hedgehog induces this pituitary marker, and thus likely pituitary cell types, in blastula cap explants (see also FIGURE 20, lane 6, for a stronger signal showing this), when compared to control explants in the absence of hedgehog (lane 2), which do not express  
25      this gene. Lane 6 shows that explants treated with activin, in the absence of hedgehog, also express the pituitary gene. Lane 8 shows that explants treated with both hedgehog, and with activin, give highest levels of the pituitary gene. Lane 10 proves that this effect

-88-

of hedgehog is specific, since prolactin, another secreted protein, does not lead to this elevated level of pituitary gene.

The panel labelled OTX-A detects this anterior brain gene. Lane 4 (and 6 in Figure 20) shows that hedgehog can induce this neural-specific gene. Lane 8 shows that the level of this neural gene is highest in tissue treated with both activin and hedgehog, relative to hedgehog alone (lane 4), or activin alone (lane 6), and control explants do not express this gene (lane 2). Again, this effect is specific to hedgehog, since prolactin (lane 10) did not lead to elevated expression of this gene. The panel labelled XAG-1 detects a cement gland-specific gene, and lane 4 shows that hedgehog induces this gene at high level.

In panel 18B, embryos were injected with N or  $\Delta$ N-C, and some animal cap explants were treated with activin before culturing until sibling embryos reached tailbud stage. Lanes 1, 2: control animal caps from uninjected embryos. Lanes 3, 4: control animal caps from uninjected embryos, treated with activin. Lanes 5, 6: animal caps from embryos injected with N and treated with activin. Lanes 7, 8: animal caps from embryos injected with  $\Delta$ N-C and treated with activin. Whereas N displays activities in activin-treated explants similar to those of *X-bhh* (see B)  $\Delta$ N-C produces the opposite effect, decreasing anterior and increasing posterior neural marker expression. As shown in Figure 18B, N behaves like *X-bhh* in that it induces elevated levels of XANF-2 and Otx-A (lane 6) relative to control activin-treated animal caps (lane 4). Moreover, N also leads to a decrease in the expression of more posterior markers, such as *krox-20* and *Xlhbox-6*, as observed following injection of *X-bhh*. In contrast to the activity of N (Fig. 4C, lane 6),  $\Delta$ N-C decreases the expression of the anterior neural genes XANF-2 or Otx-A (Fig. 4C, lane 8) in activin-treated animal caps when compared to uninjected controls (lane 4). Moreover,  $\Delta$ N-C also leads to an increase in the expression of more posterior markers, such as *En-2* and *Xlhbox-6*.

FIGURE 19 shows *X-bhh* modifies the anteroposterior pattern of neural gene expression in explants under the influence of endogenous neural inducers. (A) Isolation of dorsal

explants from injected embryos for the preparation of Keller sandwiches (Keller and Danilchik, 1988; Doniach, *et al.*, 1992; redrawn from Doniach, 1993). (B) Keller sandwiches were made from uninjected (lanes 1 and 2) and *X-bhh*-injected (lanes 3 and 4) embryos, total RNA was isolated when control embryos reached stage 20, and RT-PCR was used to analyze the expression of XAG-1 and neural markers. XAG-1 is a cement gland marker, XANF-2 is an anterior pituitary marker, Otx-A is a forebrain marker, *En-2* demarcates the midbrain-hindbrain boundary, Krox-20 marks rhombomeres 3 and 5 of the hindbrain and *XIHbox-6* is a spinal cord marker. N-CAM is a general neural marker whose expression is not restricted along the anteroposterior axis. The EF-1 $\alpha$  control demonstrates that a comparable amount of RNA was assayed in each set. Note that expression of XAG-1 and anterior neural markers is stimulated by *X-bhh* treatment, whereas expression of posterior neural markers is suppressed.

FIGURE 20 demonstration of differential activities of N and C domains of hedgehog proteins. As in FIGURE 18 above, odd numbered lanes are negative control lanes, and positive numbered lanes show specific gene expression for the markers described above. The N domain of hedgehog is encoded in the construct called Xhh1208 (lane 8), and the C domain is encoded in the construct called Xhh1delta 27-208 (lane 10). The construct Xhh11-1270A (lane 12) is specifically mutated so that it is unable to undergo self-processing. The ability of the N and C domains to induce the genes described above is compared to control blastula cap explants (lane 4), entire embryos as a positive control (lane 2), blastula cap explants expressing a mutated hedgehog as a negative control (lane 14), blastula caps expressing the entire hedgehog 1 (lane 6), and blastula cap explants treated with an independent neural inducer, noggin (lane 16) (discovered by Richard Harland at University of California at Berkeley).

Examining the first panel for the cement gland marker XAG-1 clearly shows that intact hedgehog (lane 6) and the N domain (lane 8) and the processing defective hedgehog (lane 12) are much better than inducing the cement gland than is the C domain (lane 1). Examining the second panel demonstrates that the C domain (lane 10) is better at

-90-

inducing the pituitary gene XANF1B than is the N domain (lane 8). Since the N domain induces the XAG-1 marker better, described in point A above, the two results together clearly demonstrate that the N and C domains have distinguishable activities. Examination of the remaining panels shows that all described activities of the normal hedgehog (lane 6 ) can be defined in terms of the activities of the N and C domain.

Examining the third panel, for the forebrain gene otx-A, shows that both the N domain (lane 8) and C domain (lane 10) induce similar levels of this gene, but the processing defective hedgehog (lane 12) is better than either at inducing this gene.

Examining the fourth panel of this figure (NCAM), (as well as the FIGURE 18 panels EN-2, krox20, XIHbox6, and NCAM), shows that hedgehog does not induces these more posterior neural genes. Notably, noggin (lane 16) is able to induce pituitary gene and forebrain gene, but it also induces the general neural gene, NCAM, which hedgehog does not. This clearly shows that hedgehog is a distinct activity from the neural inducer noggin, and has a more restricted ability to induce neural genes.

Experiments in the *Xenopus* embryo were conducted by injecting full-length hedgehog RNA, and immunoprecipitating with a C-domain specific antibody, which proves that full length hedgehog does in fact get processed *in vivo* in vertebrates, consistent with the data shown in earlier Examples in *Drosophila*. Thus, the ideas for the utility of detecting hedgehog N and C domains is based on knowledge that such domains do appear through hedgehog processing in vertebrates. Moreover, the knowledge that hedgehog processing does occur *in vivo* naturally raised the question of whether the resulting N and C domains have independent activity.

The results in FIGURE 18 are novel insofar as they establish that the activity of hedgehog in inducing a pituitary gene, and an anterior brain gene, may be enhanced by the TGF $\beta$  family of growth factors. This enhancement likely applies to the N and C domains described in FIGURE 20, since the genes analyzed are the same. This enhancement is due

-91-

to *hh* synergizing with neural inducing factors which are themselves induced by TGF- $\beta$  family members, including but not limited to such molecules as noggin and follistatin.

The data in FIGURE 20 makes several important points. First, the data show that the N and C domains have different though somewhat overlapping activities, and that the N and C activities added together account for all of the observed activity of the intact hedgehog protein. Thus, any clinical or diagnostic uses of hedgehog might be improved by use of the N or C domain, as one generally wishes to use the smallest protein which has an activity for clinical work, as it is less likely to evoke adverse immune responses, or other adverse side effects. Second, the data show that the C domain is better than the N domain in inducing pituitary gene expression and, since it has less induction of cement gland genes than intact hedgehog, or N domain, it suggests that the C domain might be useful in clinical situations where one wishes to enhance the development or expression of the pituitary as specifically as possible. As the pituitary is the source of a number of hormones, any treatment for enhancing pituitary cell growth and activity would ideally have as few side effects as possible, and the C domain is thus a viable candidate for therapies with enhanced pituitary cell growth and function in mind. Third, relating to studies regarding noggin, FIGURE 20 shows clearly that while both hedgehog and noggin can induce pituitary gene expression, hedgehog is more specific, since hedgehog does not induce the general neural marker NCAM, whereas noggin induces NCAM as well as pituitary. Fourth, the hedgehog which was mutated to prevent processing (lane 12) is as active as full-length and wild-type hedgehog (lane 6) in inducing pituitary gene expression, but the processing defective hedgehog is better at inducing the forebrain marker *otx-A*. Thus, for some clinical applications of hedgehog in inducing specific cell types, it is possible that the processing-defective hedgehog will be superior compared to normal hedgehog.

FIGURE 21 shows  $\Delta$ N-C interferes with X-*bhh* and N activity in animal cap explants. Embryos were injected with various RNAs, animal cap explants were cultured until sibling embryos reached tailbud (stage 25), at which time RT-PCR was used to analyze

-92-

the expression of the cement gland marker XAG-1 and the control RNA, EF-1 $\alpha$ . Lanes 1, 2: control animal caps from uninjected embryos. Lanes 3, 4: animal caps from embryos injected with both X-*bhh* and prolactin RNAs. Lanes 5, 6: animal caps from embryos injected with box X-*bhh* and  $\Delta$ N-C. Lanes 7, 8: animal caps from embryos injected with both N and prolactin RNAs. Lanes 9, 10: animal caps from embryos injected with both N and  $\Delta$ N-C. The N and X-*bhh* experiments were conducted independently and thus absolute levels in lanes 3-6 should not be compared to those in lanes 7-10. Note that the induction of XAG-1 expression by X-*bhh* or N is reduced by co-injection of  $\Delta$ N-C.

An internal deletion of X-*bhh* ( $\Delta$ N-C) blocked the activity of X-*bhh* and N in explants and reduced dorsoanterior structures in embryos. As elevated *hh* activity increases the expression of anterior neural genes, and as  $\Delta$ N-C reduces dorsoanterior structures, these complementary data support a role for *hh* in neural induction and anteroposterior patterning.

$\Delta$ N-C deletes amino acids 28-194 of X-*bhh*. The primary translation product is predicted to undergo signal sequence cleavage removing amino acids 1-23, and to undergo autoproteolysis. Based on the cleavage site in *Drosophila hh* (Porter, *et al.*, *Nature*, 374:363, 1995) autoproteolysis would generate a C domain of X-*bhh* amino acids 198-409, as well as a predicted seven amino acid polypeptide, representing amino acids 24-27, and 195-197 (Lai, *et al.*, *Development* 121:2349, 1995). Analysis of the effect of  $\Delta$ N-C on neural markers was by standard methods including Northern blot analysis and in situ hybridization (Lai, *et al.*, *supra*, incorporated herein by reference).

Although  $\Delta$ N-C does not induce the cement gland marker XAG-1, it decreases the expression of anterior ectodermal and neural markers in activin-treated animal caps. Thus,  $\Delta$ N-C has the capacity to affect neural patterning.  $\Delta$ N-C also promotes an increase in posterior neural markers in activin-treated animal caps. Mixing  $\Delta$ N-C with N or full length X-*bhh* at a 1:1 ratio led to a dramatic inhibition of the induction of cement gland in animal cap assays, supporting the hypothesis that  $\Delta$ N-C interfered with X-*hh*.

**CLAIMS**

1. A substantially pure polypeptide characterized by having an amino acid sequence derived from amino terminal amino acids of a hedgehog protein and having at its carboxy terminus, a G↓CF cleavage site specifically recognized by a proteolytic activity of the carboxy terminal fragment of the native hedgehog polypeptide.
2. An isolated polynucleotide sequence encoding a polypeptide having an amino acid sequence of claim 1.
3. The isolated polynucleotide sequence of claim 2, encoding a polypeptide having an amino acid sequence of the polypeptide of claim 1 and having at least one epitope for an antibody immunoreactive with the polypeptide of claim 1.
4. A recombinant expression vector which contains the polynucleotide of claim 2.
5. A host cell which contains the expression vector of claim 4.
6. An antibody which binds to the polypeptide of claim 1 and which binds with immunoreactive fragments of the polypeptide of claim 1.
7. The antibody of claim 6, wherein the antibody is polyclonal.
8. The antibody of claim 6, wherein the antibody is monoclonal.

-108-

9. A substantially pure polypeptide characterized by having an amino acid sequence derived from carboxy terminal amino acids of a hedgehog protein and having at its amino terminus, a G↓CF cleavage site specifically recognized by a proteolytic activity of the carboxy terminal fragment of the native hedgehog polypeptide.
10. An isolated polynucleotide sequence encoding a polypeptide having an amino acid sequence of claim 9.
11. The isolated polynucleotide sequence of claim 10, encoding a polypeptide having an amino acid sequence of the polypeptide of claim 9 and having at least one epitope for an antibody immunoreactive with the polypeptide of claim 9.
12. A recombinant expression vector which contains the polynucleotide of claim 10.
13. A host cell which contains the expression vector of claim 12.
14. An antibody which binds to the polypeptide of claim 9 and which binds with immunoreactive fragments of the polypeptide of claim 9.
15. The antibody of claim 14, wherein the antibody is polyclonal.
16. The antibody of claim 14, wherein the antibody is monoclonal.
17. A method for modulating proliferation or differentiation of neuronal cells, comprising contacting the cells with a hedgehog polypeptide.
18. The method of claim 17, wherein the hedgehog polypeptide is the polypeptide of claim 1.

-109-

19. The method of claim 17, wherein the hedgehog polypeptide is the polypeptide of claim 9.
20. The method of claim 17, wherein the modulation is induction of proliferation or differentiation.
21. The method of claim 17, wherein the neuronal cells are substantially derived from floor plate neuronal cells.
22. The method of claim 21, wherein the neuronal cells are motor neurons.
23. The method of claim 17, wherein the neuronal cells are vertebrate neuronal cells.
24. The method of claim 23, wherein the vertebrate is a human.
25. The method of claim 17, further comprising contacting the cell with a member of the TGF- $\beta$  family.
26. The method of claim 25, wherein the TGF- $\beta$  is activin.
27. The method of claim 17, further comprising contacting the cell with a neural inducing agent.
28. The method of claim 27, wherein the neural inducing agent is selected from the group consisting of noggin, follistatin, and a neurotrophin.
29. An autoproteolytic fusion protein comprising a first polypeptide including the proteolytic domain of the polypeptide of claim 9, a cleavage site recognized by the first polypeptide, and a second polypeptide.

-110-

30. A polynucleotide encoding the fusion protein of claim 29.
31. A method for producing an autoproteolytic fusion protein comprising operably linking a first polynucleotide encoding a first polypeptide including the proteolytic domain of the polypeptide of claim 9 and the cleavage site recognized by the proteolytic domain, and a second polynucleotide encoding a second polypeptide.

Lens absent	16 %	86 %	100 %	9 %	0 %
Lens smaller	48 %	9 %	0 %	36 %	0 %
Reduced eye pigment	80 %	91 %	100 %	64 %	0 %
No midbrain-hindbrain constriction	48 % (25)	77 % (44)	100 % (16)	22 % (45)	3 % (37)

The percentages of affected embryos are shown; the numbers of embryos assayed are given in parentheses. Embryos were analyzed at the indicated time-points after injection of synthetic mRNA, as described in the text and Figs 3-5. These results represent a set of assays performed together for direct comparison of activities; repetitions yielded similar results. See text and Fig. 7 for description of transcription constructs.
